INVARIANT RANDOM SUBGROUPS OF INDUCTIVE LIMITS
OF FINITE ALTERNATING GROUPS

SIMON THOMAS AND ROBIN TUCKER-DROB

Abstract. We classify the ergodic invariant random subgroups of inductive limits of finite alternating groups.

1. Introduction

A simple locally finite group \(G\) is said to be an \(L(\text{Alt})\)-group if we can express \(G = \bigcup_{i \in \mathbb{N}} G_i\) as the union of a strictly increasing chain of finite alternating groups \(G_i = \text{Alt}(\Delta_i)\). Here we allow arbitrary embeddings \(G_i \hookrightarrow G_{i+1}\). In this paper, we will classify the ergodic invariant random subgroups of the \(L(\text{Alt})\)-groups, and we will consider the relationship between the existence of “nontrivial” ergodic IRSs, “nontrivial” characters \(\chi : G \to \mathbb{C}\) and “nontrivial” 2-sided ideals \(I \subseteq \mathbb{C}G\).

Let \(G\) be a countably infinite group and let \(\text{Sub}_G\) be the compact space of subgroups \(H \leq G\). Then a Borel probability measure \(\nu\) on \(\text{Sub}_G\) which is invariant under the conjugation action of \(G\) on \(\text{Sub}_G\) is called an invariant random subgroup or IRS. For example, if \(N \triangleleft G\) is a normal subgroup, then the corresponding Dirac measure \(\delta_N\) is an IRS of \(G\). Further examples of IRSs arise from the stabilizer distributions of measure-preserving actions, which are defined as follows. Suppose that \(G\) acts via measure-preserving maps on the Borel probability space \((Z, \mu)\) and let \(f : Z \to \text{Sub}_G\) be the \(G\)-equivariant map defined by

\[
z \mapsto G_z = \{ g \in G \mid g \cdot z = z \}.
\]

Then the corresponding stabilizer distribution \(\nu = f_*\mu\) is an IRS of \(G\). In fact, by a result of Abért-Glasner-Virag [1], every IRS of \(G\) can be realized as the stabilizer distribution of a suitably chosen measure-preserving action. Moreover, by Creutz-Peterson [2], if \(\nu\) is an ergodic IRS of \(G\), then \(\nu\) is the stabilizer distribution of an ergodic action \(G \acts (Z, \mu)\).

Definition 1.1. A countably infinite group \(G\) is said to be strongly simple if the only ergodic IRSs of \(G\) are \(\delta_1\) and \(\delta_G\).

In other words, a (necessarily simple) group \(G\) is strongly simple if \(G\) has no nontrivial ergodic IRSs.

As we pointed out in Thomas-Tucker-Drob [16], if \(G\) is a countably infinite locally finite group and \(G \acts (Z, \mu)\) is an ergodic action, then an application of the Pointwise Ergodic Theorem for actions of locally finite groups to the associated character \(\chi(g) = \mu(\text{Fix}_Z(g))\) allows us to regard \(G \acts (Z, \mu)\) as the “limit” of a suitable sequence of finite permutation groups \(G_n \acts (\Omega_n, \mu_n)\), where \(\mu_n\) is the uniform probability measure on \(\Omega_n\).

Definition 1.2. If $G$ is a countable group, then the function $\chi : G \to \mathbb{C}$ is a character if the following conditions are satisfied:

(i) $\chi(gh^{-1}) = \chi(g)$ for all $g, h \in G$.
(ii) $\sum_{i,j=1}^{m} \lambda_{i} \lambda_{j} \chi(g_{i}^{-1} g_{j}) \geq 0$ for all $\lambda_{1}, \cdots, \lambda_{n} \in \mathbb{C}$ and $g_{1}, \cdots, g_{n} \in G$.
(iii) $\chi(1_{G}) = 1$.

A character $\chi$ is said to be indecomposable or extremal if it is impossible to express $\chi = r\chi_{1} + (1 - r)\chi_{2}$, where $0 < r < 1$ and $\chi_{1} \neq \chi_{2}$ are distinct characters.

The set $\mathcal{F}(G)$ of characters of $G$ always contains the two “trivial” characters $\chi_{\text{con}}$ and $\chi_{\text{reg}}$, where $\chi_{\text{con}}(g) = 1$ for all $g \in G$ and $\chi_{\text{reg}}(g) = 0$ for all $1 \neq g \in G$. It is well-known that $\chi_{\text{con}}$ is indecomposable, and that $\chi_{\text{reg}}$ is indecomposable if and only if $G$ is an i.c.c. group, i.e. the conjugacy class $gG$ of every nonidentity element $g \in G$ is infinite. (For example, see Peterson-Thom [11].) We will say that $\mathcal{F}(G)$ is trivial if every $\chi \in \mathcal{F}(G)$ is a convex combination of $\chi_{\text{con}}$ and $\chi_{\text{reg}}$.

Theorem 1.3. If the countably infinite simple group $G$ is not strongly simple, then $\mathcal{F}(G)$ is nontrivial.

Proof. Suppose that $\nu \neq \delta_{1}, \delta_{G}$ is a nontrivial ergodic IRS of $G$. Then, by Creutz-Peterson [2, Proposition 3.3.1], we can suppose that $\nu$ is the stabilizer distribution of an ergodic action $G \actson (Z, \mu)$. Let $\chi(g) = \mu(\text{Fix}_{Z}(g))$ be the associated character. Suppose that there exists $0 < r < 1$ such that $\chi = r\chi_{\text{con}} + (1 - r)\chi_{\text{reg}}$. Then, since $\nu \neq \delta_{1}, \delta_{G}$, it follows that $0 < r < 1$; and so $\inf_{g \in G} \mu(\text{Fix}_{Z}(g)) = r > 0$. Applying Ioana-Kechris-Tsankov [5, Theorem 1(i)] in the special case when $E$ is the identity relation, it follows that there exists a positive integer $m \leq 1/r$ and a Borel subset $A \subseteq Z$ with $\mu(A) > 0$ such that $|G \cdot a \cap A| = m$ for all $a \in A$. (Here $G \cdot a$ denotes the $G$-orbit $\{g(a) \mid g \in G\}$.) Fix some Borel linear ordering $\preceq$ of $Z$ and let $T \subseteq A$ be the subset defined by

$$t \in T \iff t \text{ is the } \preceq\text{-least element of } G \cdot t \cap A.$$  

Then $T$ is a Borel subset of $Z$ such that $\mu(T) = \mu(A)/m > 0$ with the property that if $t \neq t' \in T$, then $G \cdot t \neq G \cdot t'$. Since $G$ acts ergodically on $(Z, \mu)$, it follows that there exists a point $t_{0} \in T$ such that $\mu(\{t_{0}\}) = \mu(T) > 0$; and this implies that $G \cdot t_{0}$ is a finite orbit and that $\mu(G \cdot t_{0}) = 1$. Since $G$ is an infinite simple group, it follows that $G$ acts trivially on the finite set $G \cdot t_{0}$ and hence $\mu(\{t_{0}\}) = 1$. But this means that $\nu = \delta_{G}$, which is a contradiction. Consequently, $\chi(g)$ is not a convex combination of $\chi_{\text{con}}$ and $\chi_{\text{reg}}$. \hfill \Box

There exist examples of ergodic actions $G \actson (Z, \mu)$ of countably infinite groups such that the associated character $\chi$ is not indecomposable. For example, if the ergodic action $G \actson (Z, \mu)$ is essentially free, then $\chi = \chi_{\text{reg}}$, and so $\chi$ is indecomposable if and only if $G$ is an i.c.c. group. There also exist more interesting examples.

Theorem 1.4. There exists an ergodic action $\text{Alt}(\mathbb{N}) \actson (Z, \mu)$ such that the associated character is not indecomposable.

Proof. Suppose that $\chi$ is an indecomposable character of the infinite alternating group $\text{Alt}(\mathbb{N})$. Then, by Thoma [15, Satz 6], there exists an indecomposable character $\theta$ of the group $\text{Fin}(\mathbb{N})$ of finitary permutations of the natural numbers such that $\chi = \theta \upharpoonright \text{Alt}(\mathbb{N})$; and hence, by Thoma [15, Satz 1], we have that

\begin{equation}
\chi((1, 2), (3, 4), (5, 6), (7, 8)) = \chi((1, 2), (3, 4)) \chi((5, 6), (7, 8)).
\end{equation}
Thus it suffices to find an ergodic action $\text{Alt}(\mathbb{N}) \curvearrowright (\mathbb{Z}, \mu)$ such that the associated character $\chi(g) = \mu(\text{Fix}_Z(g))$ fails to satisfy the multiplicative property (1.1).

Let $m$ be the usual uniform product probability measure on $2^\mathbb{N}$. Then $\text{Alt}(\mathbb{N})$ acts ergodically on $(2^\mathbb{N}, m)$ via the shift action $(g \cdot \xi)(n) = \xi(g^{-1}(n))$. For each $\xi \in 2^\mathbb{N}$ and $i = 0, 1$, let $B_i^s = \{ n \in \mathbb{N} \mid \xi(n) = i \}$. Let $f : 2^\mathbb{N} \rightarrow \text{Sub}_{\text{Alt}(\mathbb{N})}$ be the $\text{Alt}(\mathbb{N})$-equivariant map defined by $\xi \mapsto \text{Alt}(B_0^s) \times \text{Alt}(B_1^s)$ and let $\nu = f_*m$ be the corresponding ergodic IRS of $\text{Alt}(\mathbb{N})$. Then, by Creutz-Peterson [2], $\nu$ is the stabilizer distribution of an ergodic action $\text{Alt}(\mathbb{N}) \curvearrowright (\mathbb{Z}, \mu)$; and the associated character $\chi$ is given by

$$\chi(g) = \mu(\text{Fix}_Z(g)) = \nu(\{ H \in \text{Sub}_{\text{Alt}(\mathbb{N})} \mid g \in H \}) = m(\{ \xi \in 2^\mathbb{N} \mid g \in \text{Alt}(B_0^s) \times \text{Alt}(B_1^s) \}).$$

Clearly $(1 2) (3 4) \in \text{Alt}(B_0^s) \times \text{Alt}(B_1^s)$ if and only if $\xi(1) = \xi(2) = \xi(3) = \xi(4)$; and it follows that

$$\chi((1 2) (3 4)) = \chi((56) (78)) = 1/2^4 + 1/2^4 = 1/2^3.$$

On the other hand, we have that

$$\chi((1 2) (3 4) (56) (78)) = \left(\begin{array}{c} 4 \\ 0 \end{array}\right) + \left(\begin{array}{c} 4 \\ 1 \end{array}\right) + \left(\begin{array}{c} 4 \\ 2 \end{array}\right) = 1/2^5.$$

Since the multiplicative property (1.1) fails, it follows that $\chi$ is not indecomposable.

\[\square\]

**Problem 1.5.** Find necessary and sufficient conditions for the associated character of an ergodic action $G \curvearrowright (\mathbb{Z}, \mu)$ to be indecomposable.

Vershik [18] has proved a very interesting sufficient condition; namely, that if $G \curvearrowright (\mathbb{Z}, \mu)$ is ergodic and $N_G(g_z) = G_z$ for $\mu$-a.e. $z \in \mathbb{Z}$, then the associated character is indecomposable. Using Vershik’s criterion, together with our classification of the ergodic IRSs of the $L(G)$-groups $G \not\cong \text{Alt}(\mathbb{N})$, we will prove the following result.

**Theorem 1.6.** If $G \not\cong \text{Alt}(\mathbb{N})$ is an $L(G)$-group and $G \curvearrowright (\mathbb{Z}, \mu)$ is an ergodic action, then the associated character is indecomposable.

It is clear from Theorems 1.4 and 1.6 that $\text{Alt}(\mathbb{N})$ plays an exceptional role within the class of $L(G)$-groups. In Section 9, adapting and slightly correcting Vershik’s analysis of the ergodic IRSs of the group $\text{Fin}(\mathbb{N})$ of finitary permutations of the natural numbers, we will state the classification of the ergodic IRSs of $\text{Alt}(\mathbb{N})$ and we will characterize the ergodic actions $\text{Alt}(\mathbb{N}) \curvearrowright (\mathbb{Z}, \mu)$ such that the associated character $\chi(g) = \mu(\text{Fix}_Z(g))$ is indecomposable.

The $L(G)$-groups with a nontrivial ergodic IRS will be classified as follows. Suppose that $G = \bigcup_{i \in \mathbb{N}} G_i$ is the union of the strictly increasing chain of finite alternating groups $G_i = \text{Alt}(\Delta_i)$, where $|\Delta_0| \geq 5$. For each $i \in \mathbb{N}$, let $s_{i+1}$ be the number of natural orbits of $G_i$ on $\Delta_{i+1}$ and let $c_{i+1}$ be the number of points $x \in \Delta_{i+1}$ which lie in a nontrivial non-natural $G_{i}$-orbit. (Here an orbit $\Omega$ of $G_i = \text{Alt}(\Delta_i)$ on $\Delta_{i+1}$ is said to be natural if $|\Omega| = |\Delta_i|$ and the action $G_i \curvearrowright \Omega$ is isomorphic to the natural action $G_i \curvearrowright \Delta_i$.) Also for each $i < j$, let $s_{ij} = s_{i+1} s_{i+2} \cdots s_j$. Recall that $G = \bigcup_{i \in \mathbb{N}} G_i$ is said to be a diagonal limit if $s_{i+1} > 0$
and $c_{i+1} = 0$ for all $i \in \mathbb{N}$; i.e. if for each $i \in \mathbb{N}$, every $G_i$-orbit on $\Delta_{i+1}$ is either natural or trivial.

**Definition 1.7.** $G = \bigcup_{i \in \mathbb{N}} G_i$ is an almost diagonal limit if $s_{i+1} > 0$ for all $i \in \mathbb{N}$ and $\sum_{i=1}^{\infty} e_i/s_0 < \infty$.

**Theorem 1.8.** If $G$ is an $L(\text{Alt})$-group, then $G$ has a nontrivial ergodic IRS if and only if $G$ can be expressed as an almost diagonal limit of finite alternating groups.

We will present an explicit classification of the ergodic IRSs of the $L(\text{Alt})$-groups $G \not\cong \text{Alt}(\mathbb{N})$ in Sections 3 and 4. The classification involves a fundamental dichotomy which was originally introduced by Leinen-Puglisi [9, 10] in the more restrictive setting of diagonal limits of alternating groups, i.e. the linear vs sub-linear natural orbit growth condition. This dichotomy arose unexpectedly in the restrictive setting of diagonal limits of alternating groups, i.e. the linear vs sub-linear natural orbit growth condition. This dichotomy which was originally introduced by Leinen-Puglisi [9, 10] in the more restrictive setting of diagonal limits of alternating groups, i.e. the linear vs sub-linear natural orbit growth condition. This dichotomy arose unexpectedly in the work of Leinen-Puglisi [9, 10] without any natural explanation. By contrast, in this paper, it will appear as a natural consequence of the Pointwise Ergodic Theorem for actions of locally finite groups.

In [19], Vershik showed that the indecomposable characters of the group $\text{Fin}(\mathbb{N})$ of finitary permutations of the natural numbers were very closely connected with the ergodic IRSs of $\text{Fin}(\mathbb{N})$; and in [18], he suggested that this should also be true of various other locally finite groups. Combining our classification of the ergodic IRSs of the $L(\text{Alt})$-groups with the earlier work of Leinen-Puglisi [10], it follows that if $G = \bigcup_{i \in \mathbb{N}} G_i$ is a diagonal limit of finite alternating groups and $G \not\cong \text{Alt}(\mathbb{N})$, then the indecomposable characters of $G$ are precisely the associated characters of the ergodic IRSs of $G$.

**Question 1.9.** Does there exist a strongly simple locally finite group $G$ such that $F(G)$ is nontrivial?

If $G$ is a countable group and $\chi \in F(G)$ is a character, then we can extend $\chi$ to a linear function $\chi : CG \to \mathbb{C}$ and define a corresponding proper 2-sided ideal $I_{\chi}$ of the group ring $CG$ by

$$I_{\chi} = \{ x \in CG \mid \chi(gx) = 0 \text{ for all } g \in G \}. $$

For example, let $\omega(CG)$ be the augmentation ideal, i.e. the kernel of the homomorphism $CG \to \mathbb{C}$ defined by $\sum \lambda_i g_i \mapsto \sum \lambda_i$. Then it is easily checked that if $\chi$ is a character of $G$, then $I_{\chi} = \omega(CG)$ if and only if $\chi = \chi_{\text{con}}$. It is also easily seen that $I_{\chi_{\text{reg}}} = \{ 0 \}$. In [22], Zalesskii asked whether there exists a simple locally finite group $G$ with an indecomposable character $\chi \neq \chi_{\text{reg}}$ such that $I_{\chi} = \{ 0 \}$; and he conjectured that if $G$ is a simple locally finite group such that $\omega(CG)$ is the only nontrivial proper 2-sided ideal of $CG$, then $F(G)$ is trivial. In Section 3, we will give an example of a simple locally finite group $G$ such that:

(a) the augmentation ideal $\omega(CG)$ is the only nontrivial proper 2-sided ideal of $CG$; and

(b) $G$ has infinitely many indecomposable characters $\chi$ such that $I_{\chi} = \{ 0 \}$.

It should be pointed out that Leinen-Puglisi [9] gave the first examples of simple locally finite groups $G$ with indecomposable characters $\chi \neq \chi_{\text{reg}}$ such that $I_{\chi} = \{ 0 \}$. However, in their examples, the corresponding group rings $CG$ had infinitely many nontrivial proper 2-sided ideals.

This paper is organized as follows. In Section 2, we will briefly discuss the pointwise ergodicity and weak mixing properties of ergodic actions of countably
The Pointwise Ergodic Theorem. With the above hypotheses, if $B \subseteq Z$ is a $\mu$-measurable subset, then for $\mu$-a.e. $z \in Z$,

$$
\mu(B) = \lim_{i \to \infty} \frac{1}{|G_i|} |\{ g \in G_i | g \cdot z \in B \}|
$$

In particular, the Pointwise Ergodic Theorem applies when $B$ is the $\mu$-measurable subset $\text{Fix}_Z(g) = \{ z \in Z | g \cdot z = z \}$ for some $g \in G$. For each $z \in Z$ and $i \in \mathbb{N}$, let $\Omega_i(z) = \{ g \cdot z | g \in G_i \}$ be the corresponding $G_i$-orbit. Then, as pointed out in Thomas-Tucker-Drob [16, Theorem 2.1], the following result is an easy consequence of the Pointwise Ergodic Theorem.

Theorem 2.1. With the above hypotheses, for $\mu$-a.e. $z \in Z$, for all $g \in G$,

$$
\mu(\text{Fix}_Z(g)) = \lim_{i \to \infty} |\text{Fix}_{\Omega_i(z)}(g)|/|\Omega_i(z)|
$$

The normalized permutation character $|\text{Fix}_{\Omega_i(z)}(g)|/|\Omega_i(z)|$ is the probability that an element of $(\Omega_i(z),\mu_i)$ is fixed by $g \in G_i$, where $\mu_i$ is the uniform probability measure on $\Omega_i(z)$; and, in this sense, we can regard $G \rtimes (Z,\mu)$ as the “limit” of the sequence of finite permutation groups $G_i \rtimes (\Omega_i(z),\mu_i)$. Of course, the
permutation group \( G_i \cap \Omega(z) \) is isomorphic to \( G_i \cap G_i/H_i \), where \( G_i/H_i \) is the set of cosets of \( H_i = \{ h \in G_i \mid h \cdot z = z \} \) in \( G_i \). The following simple observation will be used repeatedly in our later applications of Theorem 2.1. (For example, see Thomas-Tucker-Drob [16, Proposition 2.2].)

**Proposition 2.2.** If \( H \leq A \) are finite groups and \( \theta \) is the normalized permutation character corresponding to the action \( A \rtimes A/H \), then

\[
\theta(g) = \frac{|g^A \cap H|}{|g^A|} = \left| \left\{ s \in A \mid sgs^{-1} \in H \right\} \right|.
\]

The following consequence of Proposition 2.2 implies that when computing upper bounds for the normalized permutation characters of actions \( A \rtimes A/H \), we can restrict our attention to those coming from maximal subgroups \( H < A \).

**Corollary 2.3.** If \( H \leq H' \leq A \) are finite groups and \( \theta, \theta' \) are the normalized permutation characters corresponding to the actions \( A \rtimes A/H \) and \( A \rtimes A/H' \), then \( \theta(g) \leq \theta'(g) \) for all \( g \in A \).

Finally we point out the following straightforward but useful observations.

**Theorem 2.4.** If \( G \) is a countably infinite simple locally finite group, then every ergodic action \( G \rtimes (Z, \mu) \) is weakly mixing.

**Proof.** Suppose that the ergodic action \( G \rtimes (Z, \mu) \) is not weakly mixing. Then, by Schmidt [13, Proposition 2.2], it follows that \( G \) has a nontrivial finite dimensional unitary representation; and since \( G \) is simple, this representation is necessarily faithful. However, this is impossible since Schur [14] has proved that every locally finite linear group over the complex field has an abelian subgroup of finite index. (For a more accessible reference, see Curtis-Reiner [3, Theorem 36.14].) \( \square \)

**Corollary 2.5.** If \( G \) is a countably infinite simple locally finite group and the action \( G \rtimes (Z, \mu) \) is ergodic, then the product action \( G \rtimes \left( Z', \mu^{\otimes r} \right) \) is also ergodic for every \( r \geq 2 \).

3. Linear natural orbit growth

In this section, we will begin our analysis of the ergodic IRSs of the \( L(\text{Alt}) \)-groups \( G \cong \text{Alt}(\mathbb{N}) \). First we need to introduce some notation. For the remainder of this paper, suppose that \( G = \bigcup_{i \in \mathbb{N}} G_i \) is the union of the strictly increasing chain of finite alternating groups \( G_i = \text{Alt}(\Delta_i) \), where \( |\Delta_0| \geq 5 \). For each \( i \in \mathbb{N} \), let

- \( n_i = |\Delta_i| \);
- \( s_{i+1} \) be the number of natural orbits of \( G_i \) on \( \Delta_{i+1} \);
- \( f_{i+1} \) be the number of trivial orbits of \( G_i \) on \( \Delta_{i+1} \);
- \( e_{i+1} = n_{i+1} - (s_{i+1}n_i + f_{i+1}) \); and
- \( t_{i+1} = e_{i+1} + f_{i+1} \).

Thus \( e_{i+1} \) is the number of points \( x \in \Delta_{i+1} \) which lie in a nontrivial non-natural \( G_i \)-orbit and \( t_{i+1} = n_{i+1} - s_{i+1}n_i \) is the number of points \( x \in \Delta_{i+1} \) which lie in a (possibly trivial) non-natural \( G_i \)-orbit. For each \( i < j \), let \( s_{ij} = s_{i+1}s_{i+2} \cdots s_j \).

**Remark 3.1.** Clearly, \( G_i \) has at least \( s_{ij} \) natural orbits on \( \Delta_j \). However, it is easy to construct examples for which \( G_i \) has strictly more than \( s_{ij} \) natural orbits on \( \Delta_j \).

For example, suppose that:

- \( \Delta_{i+1} = \Delta_i \cup \{ \alpha \} \), with \( G_i \) acting naturally on \( \Delta_i \) and fixing the point \( \alpha \);
Remark 3.3. Suppose that $G$ is an almost diagonal limit in the sense of Lavrenyuk-Nekrashevych [7].

Definition 3.2. $G = \bigcup_{i \in \mathbb{N}} G_i$ is an almost diagonal limit if $s_{i+1} > 0$ for all $i \in \mathbb{N}$ and $\sum_{i=1}^{\infty} e_i/s_0 < \infty$.

Remark 3.4. Suppose that $G = \bigcup_{i \in \mathbb{N}} G_i$ is a diagonal limit in the sense of Lavrenyuk-Nekrashevych [7].

The following observation will be used repeatedly throughout this paper.

Proposition 3.4. Suppose that $G = \bigcup_{i \in \mathbb{N}} G_i$ is an almost diagonal limit of the finite alternating groups $G_i = \text{Alt}(\Delta_i)$. If $(j_i \mid i \in \mathbb{N})$ is a strictly increasing sequence of natural numbers and $G'_i = \text{Alt}(\Delta_{j_i})$, then $G = \bigcup_{i \in \mathbb{N}} G'_i$ is also an almost diagonal limit.

Proof. For each $i < j$, let $e_{ij}$ be the number of points $x \in \Delta_j$ which lie in a nontrivial non-natural $G_i$-orbit. Then an easy induction on $j \geq i + 1$ shows that

$$e_{ij} \leq \sum_{k=i+1}^{j-1} s_k e_k + e_j.$$

Let $e'_{i+1}$, $s'_{i+1}$ be the corresponding parameters for the increasing union $G = \bigcup_{i \in \mathbb{N}} G'_i$. Then $e'_{i+1} = e_{j_i j_{i+1}}$ and $s'_{i+1} \geq s_{j_i+1} \cdots s_{j_{i+1}}$. It follows that

$$s'_0 e_{0j} = s'_1 \cdots s'_{i+1} \geq (s_{j_0+1} \cdots s_{j_i}) \cdots (s_{j_{i+1}+1} \cdots s_{j_{i+2}}) = s^{-1}_{0j} s_{0j_{i+1}}$$

and hence we obtain that

$$e'_{i+1}/s'_{0j+1} \leq \frac{s_{0j}}{s_{0j_{i+1}}} \sum_{k=j_i+1}^{j_{i+1}-1} s_k e_k + e_{j_i+1}$$

$$= s_{0j} \sum_{k=j_i+1}^{j_{i+1}} e_k/s_{0k}.$$

The result follows.

Remark 3.5. Suppose that $G = \bigcup_{i \in \mathbb{N}} G_i$ is an almost diagonal limit of finite alternating groups. If $s_{i+1} = 1$ for all but finitely many $i \in \mathbb{N}$, then $e_{i+1} = 0$ for all but finitely many $i \in \mathbb{N}$, and it follows that $G \cong \text{Alt}(\mathbb{N})$. Hence, applying Proposition 3.4, if $G \not\cong \text{Alt}(\mathbb{N})$, then we can suppose that the almost diagonal limit $\bigcup_{i \in \mathbb{N}} G_i$ has been chosen such that $s_{i+1} > 1$ for all $i \in \mathbb{N}$.

Definition 3.6. The $L(\text{Alt})$-group $G$ has almost diagonal type if $G$ can be expressed as an almost diagonal limit of finite alternating groups.

We are now in a position to state the first of the main results of this paper.

Theorem 3.7. If $G$ is an $L(\text{Alt})$-group, then $G$ has a nontrivial ergodic IRS if and only if $G$ has almost diagonal type.

The classification of the ergodic IRSs of the groups of almost diagonal type involves a fundamental dichotomy which was introduced by Leinen-Puglisi [9, 10] in the more restrictive setting of diagonal limits of alternating groups, i.e. the linear vs sublinear natural orbit growth condition. The statement and proof of the
following lemma are identical to Leinen-Puglisi [10, Lemma 2.2]. (Note that the following lemma does not require that $G = \bigcup_{i \in \mathbb{N}} G_i$ is an almost diagonal limit.)

**Lemma 3.8.** For each $i \in \mathbb{N}$, the limit $a_i = \lim_{j \to \infty} s_{ij}/n_j$ exists.

**Proof.** If $i < j < k$, then $s_{ik} = s_{ij}s_{jk}$ and clearly $n_j s_{jk} \leq n_k$. Hence

$$\frac{s_{ik}}{n_k} = \frac{s_{ij}}{n_j} \cdot \frac{n_j s_{jk}}{n_k} \leq \frac{s_{ij}}{n_j}$$

and the sequence $(s_{ij}/n_j | i < j \in \mathbb{N})$ converges to $\inf_{j \geq i} s_{ij}/n_j$. \qed

**Definition 3.9.** $G = \bigcup_{i \in \mathbb{N}} G_i$ has linear natural orbit growth if $a_i > 0$ for some $i \in \mathbb{N}$. Otherwise, $G = \bigcup_{i \in \mathbb{N}} G_i$ has sublinear natural orbit growth.

**Remark 3.10.** We will soon see that if $G = \bigcup_{i \in \mathbb{N}} G_i$ has linear natural orbit growth, then $G$ has almost diagonal type.

**Remark 3.11.** Note that $a_i = s_{i+1} + a_{i+1}$. Thus $G$ has linear natural orbit growth if and only if $a_i > 0$ for all but finitely many $i \in \mathbb{N}$.

We will next prove that if $G = \bigcup_{i \in \mathbb{N}} G_i$ has linear natural orbit growth, then $G$ has a nontrivial ergodic IRS. Note that if $G = \bigcup_{i \in \mathbb{N}} G_i$ has linear natural orbit growth, then $s_{i+1} > 0$ for all but finitely many $i \in \mathbb{N}$. Hence, after replacing the increasing union $G = \bigcup_{i \in \mathbb{N}} G_i$ by $G = \bigcup_{n \leq i \in \mathbb{N}} G_i$ for some suitably chosen $n \in \mathbb{N}$, we can suppose that $s_{i+1} > 0$ for all $i \in \mathbb{N}$. We will initially work with this strictly weaker hypothesis. As we will see, the linear vs sublinear natural orbit growth dichotomy will appear naturally in our analysis via an application of the Pointwise Ergodic Theorem for actions of locally finite groups. Let $t_0 = n_0$ and recall that $t_{i+1} = e_i + 1 = n_{i+1} - s_{i+1} n_i$. Clearly we can suppose that:

- $\Delta_0 = \{ \alpha_0^\ell \mid \ell < t_0 \}$; and
- $\Delta_{i+1} = \{ \sigma^\sim k \mid \sigma \in \Delta_i, 0 \leq k < s_{i+1} \} \cup \{ \alpha_{t+1}^\ell \mid 0 \leq \ell < t_{i+1} \}$;

and that the embedding $\varphi_i : \text{Alt}(\Delta_i) \to \text{Alt}(\Delta_{i+1})$ satisfies

$$\varphi_i(g)(\sigma^\sim k) = g(\sigma)^\sim k$$

for each $\sigma \in \Delta_i$ and $0 \leq k < s_{i+1}$. Let $\Delta$ consist of all sequences of the form $(\alpha_i^k, k_{i+1}, k_{i+2}, k_{i+3}, \cdots)$, where $i \in \mathbb{N}$ and $k_j$ is an integer such that $0 \leq k_j < s_j$. For each $i \in \mathbb{N}$ and $\sigma \in \Delta_i$, let $\Delta(\sigma) \subseteq \Delta$ be the subset of sequences of the form $\sigma^\sim (k_{i+1}, k_{i+2}, k_{i+3}, \cdots)$. Then the sets $\Delta(\sigma)$ form a clopen basis for a locally compact topology on $\Delta$. (This is a special case of the “space of paths” of Lavrenyuk-Nekrashevych [7].) Consider the action $G \acts \Delta$ defined by

$$g \cdot (\alpha_i^k, k_{i+1}, k_{j+1}, \cdots) = (g(\alpha_i^k, k_{i+1}, \cdots, k_j), k_{j+1}, \cdots), \quad g \in G_j.$$  

Then we will show that there exists a $G$-invariant ergodic probability measure on $\Delta$ if and only if $G = \bigcup_{i \in \mathbb{N}} G_i$ has linear natural orbit growth; in which case, the action $G \acts \Delta$ is uniquely ergodic.

Of course, if $m$ is a $G$-invariant ergodic probability measure on $\Delta$, then $m$ is uniquely determined by $m \restriction \mathcal{A}$, where $\mathcal{A}$ is the algebra of Borel subsets of $\Delta$ generated by the basic clopen sets $\{ \Delta(\sigma) \mid \sigma \in \bigcup_{i \in \mathbb{N}} \Delta_i \}$.

**Lemma 3.12.** If $m$ is a $G$-invariant ergodic probability measure on $\Delta$ and $\sigma \in \Delta_i$, then $m(\Delta(\sigma)) = a_i$. 

Corollary 3.13. With the above hypotheses, if $G = \bigcup_{i \in \mathbb{N}} G_i$ has sublinear natural orbit growth, then there does not exist a $G$-invariant ergodic probability measure on $\Delta$.

Proof. If $G = \bigcup_{i \in \mathbb{N}} G_i$ has sublinear natural orbit growth and $m$ is a $G$-invariant ergodic probability measure on $\Delta$, then
\[
1 = m(\Delta) = \sum_{i \in \mathbb{N}} \sum_{0 \leq t < t_i} m(\Delta(\alpha_i^t)) = \sum_{i \in \mathbb{N}} t_i a_i = 0,
\]
which is a contradiction. \qed

For each $i < j$, let $t_{ij} = n_j - s_{ij} n_i$. In order to simplify notation, we will continue to write $t_{i+1}$ instead of $t_{ii+1}$. Applying Lemma 3.8, it follows that the limit $b_i = \lim_{j \to \infty} t_{ij} / n_j$ exists and that $b_i = 1 - n_i a_i$. Thus we obtain:

Lemma 3.14. If $m$ is a $G$-invariant ergodic probability measure on $\Delta$ and $i \in \mathbb{N}$, then $m(\bigcup \{ \{ \Delta(\alpha_i^t) \mid i < j, \ell < t_j \} \}) = b_i$.

Note that if $A \in \mathcal{A}$, then there exists $i \in \mathbb{N}$ and $S \subseteq \Delta_i$ such that either
(a) $A = \bigcup \{ \{ \Delta(\sigma) \mid \sigma \in S \} \}$; or
(b) $A = \bigcup \{ \{ \Delta(\sigma) \mid \sigma \in S \} \cup \{ \Delta(\alpha_i^t) \mid i < j, \ell < t_j \} \}$.

Furthermore, by Lemmas 3.12 and 3.14, if $m$ is a $G$-invariant ergodic probability measure on $\Delta$, then $m_0 = m \upharpoonright \mathcal{A}$ must be defined by
\[
m_0(A) = \begin{cases} |S| a_i, & \text{if (a) holds;} \\ |S| a_i + b_i, & \text{if (b) holds.} \end{cases}
\]

Since $a_{i+1} = a_i / s_{i+1}$ and $b_i = t_{i+1} a_{i+1} + b_{i+1}$, it follows that $m_0$ is well-defined. It is also clear that $m_0(\Delta) = 1$ and that $m_0$ is $G$-invariant. Of course, it still remains to be proved that $m_0$ is $\sigma$-additive. As we will soon see, this is an easy consequence of the following result.

Lemma 3.15. If $s_{i+1} > 0$ for all $i \in \mathbb{N}$ and $G = \bigcup_{i \in \mathbb{N}} G_i$ has linear natural orbit growth, then $\lim_{i \to \infty} b_i = 0$. 
The proof of Lemma 3.15 will make use of the following result.

**Lemma 3.16.** If \( s_{i+1} > 0 \) for all \( i \in \mathbb{N} \), then the following are equivalent:

(i) \( G = \bigcup_{i \in \mathbb{N}} G_i \) has linear natural orbit growth.

(ii) \( \sum_{k=1}^{\infty} t_k/s_{0k} < \infty \).

**Proof.** An easy induction shows that if \( j > 0 \), then

\[
n_j = s_0 j n_0 + \sum_{k=1}^{j-1} s_k t_k + t_j
\]

and hence

\[
n_j = s_0 j n_0 + \sum_{k=1}^{j} \frac{t_k}{s_{0k}}.
\]

Since \( s_{i+1} > 0 \) for all \( i \in \mathbb{N} \), it follows that \( G = \bigcup_{i \in \mathbb{N}} G_i \) has linear natural orbit growth if and only if \( a_0 = \inf_{j>0} s_0 j n_j > 0 \). The result follows.

**Remark 3.17.** Since \( e_k \leq t_k \), it follows that if \( s_{i+1} > 0 \) for all \( i \in \mathbb{N} \) and \( G = \bigcup_{i \in \mathbb{N}} G_i \) has linear natural orbit growth, then \( G = \bigcup_{i \in \mathbb{N}} G_i \) is an almost diagonal limit.

**Proof of Lemma 3.15.** Another easy induction shows that if \( j > i \), then

\[
t_{ij} = \sum_{k=i+1}^{j-1} s_k t_k + t_j.
\]

It follows that

\[
t_{ij} = s_0 j n_0 + \sum_{k=i+1}^{j} \left( \frac{t_k}{s_{0k}} \right).
\]

and hence

\[
b_i = a_0 \sum_{k=i+1}^{\infty} \frac{t_k}{s_{0k}}.
\]

Since \( \sum_{i=1}^{\infty} t_i/s_{0i} < \infty \), it follows that \( b_i \to 0 \) as \( i \to \infty \).

**Proposition 3.18.** If \( G = \bigcup_{i \in \mathbb{N}} G_i \) has linear natural orbit growth, then the action \( G \curvearrowright \Delta \) is uniquely ergodic.

**Proof.** Since any probability measure \( \mu \) on \( \Delta \) is uniquely determined by \( \mu \upharpoonright A \), it is already clear that there exists at most one \( G \)-invariant ergodic probability measure on \( \Delta \). Hence it is enough to show that the function \( m_0 \), defined by (3.1), can be extended to a \( G \)-invariant probability measure on \( \Delta \). Since \( a_k = a_0/s_{0k} \), equation (3.2) implies that

\[
b_i = a_0 \sum_{k=i+1}^{\infty} \frac{t_k}{s_{0k}} = \sum_{k=i+1}^{\infty} t_k a_k;
\]

and it follows easily that \( m_0 \) is \( \sigma \)-additive. Thus \( m_0 \) is a pre-measure on \( A \). By the Carathéodory Extension Theorem, \( m_0 \) can be extended to a probability measure \( m \) on \( \Delta \); and since \( m_0 \) is \( G \)-invariant, it follows that \( m \) is also \( G \)-invariant.
Applying Corollary 2.5, if $G = \bigcup_{i \in \mathbb{N}} G_i$ has linear natural orbit growth, then the action $G \acts (\Delta^r, m^{\otimes r})$ is also ergodic for all $r \geq 2$, and hence the corresponding stabilizer distribution $\nu_r$ is an ergodic IRS of $G$. We are now in a position to state the second of the main results of this paper.

**Theorem 3.19.** If $G = \bigcup_{i \in \mathbb{N}} G_i$ has linear natural orbit growth, then the ergodic IRSs of $G$ are $\{ \delta_1, \delta_G \} \cup \{ \nu_r \mid r \in \mathbb{N}^+ \}$.

In particular, if $G = \bigcup_{i \in \mathbb{N}} G_i$ has linear natural orbit growth, then the collection $\{ \nu_r \mid r \in \mathbb{N}^+ \}$ is independent of the particular expression of $G$ as a limit with linear natural orbit growth. From now on, whenever $G = \bigcup_{i \in \mathbb{N}} G_i$ has linear natural orbit growth, then we will refer to $G \acts (\Delta, m)$ as the canonical ergodic action. The following observation will be used repeatedly throughout this paper.

**Proposition 3.20.** If $G = \bigcup_{i \in \mathbb{N}} G_i$ has linear natural orbit growth and $r \geq 1$, then $G_2$ is self-normalizing for $m^{\otimes r}$-a.e. $\bar{x} \in \Delta^r$.

**Proof.** Let $\bar{x} = (x_1, \ldots, x_r) \in \Delta^r$ and let $G_2 = \{ g \in G \mid g \cdot x_\ell = x_\ell \text{ for } 1 \leq \ell \leq r \}$ be the corresponding stabilizer. Then it is easily checked that

$$\text{Fix}_x(G_2) = \{ x_\ell \mid 1 \leq \ell \leq r \}.$$  

Suppose that $g \in N_G(G_2) \setminus G_2$. Then $g$ permutes the elements of the set $\text{Fix}_x(G_2)$ nontrivially, and hence there exist $1 \leq \ell < m \leq r$ such that $g \cdot x_\ell = x_m$. But this implies that the sequences $x_\ell$ and $x_m$ are eventually equal; and it is clear that for $m^{\otimes r}$-a.e. $\bar{x} = (x_1, \ldots, x_r) \in \Delta^r$, if $1 \leq \ell < m \leq r$, then $x_\ell$ and $x_m$ are not eventually equal. Hence $G_2$ is self-normalizing for $m^{\otimes r}$-a.e. $\bar{x} \in \Delta^r$. \hfill \square

We are now ready to present the proof of Theorem 1.6. So suppose that $G$ is an $L(\text{Alt})$-group with $G \not\cong \text{Alt}(\mathbb{N})$ and that $G \acts (Z, \mu)$ is an ergodic action. Let $\nu$ be the corresponding stabilizer distribution and let $\chi(g) = \mu(\text{Fix}_Z(g))$ be the associated character. By Theorem 3.7, if $G$ does not have almost diagonal type, then $\nu \in \{ \delta_1, \delta_G \}$ and so $\chi \in \{ \chi_{\text{reg}}, \chi_{\text{con}} \}$, and it follows that $\chi$ is indecomposable. Hence we can suppose that $G$ has almost diagonal type; and so Theorem 1.6 is a consequence of the following result.

**Theorem 3.21.** If $G \not\cong \text{Alt}(\mathbb{N})$ has almost diagonal type and $G \acts (Z, \mu)$ is an ergodic action, then the associated character $\chi(g) = \mu(\text{Fix}_Z(g))$ is indecomposable.

**Proof.** Let $\nu$ be the stabilizer distribution of the ergodic action $G \acts (Z, \mu)$. Then, as above, we can suppose that $\nu \neq \delta_1, \delta_G$. Express $G = \bigcup_{i \in \mathbb{N}} G_i$ as an almost diagonal limit of finite alternating groups $G_i = \text{Alt}(\Delta_i)$. Let $\tau = \sum_{i=1}^\infty e_i/s_{0i} < \infty$. By Remark 3.5, since $G \not\cong \text{Alt}(\mathbb{N})$, we can suppose that $s_{i+1} > 1$ for all $i \in \mathbb{N}$. Of course, since $G_i$ is simple, this implies that if $1 \neq G'_i \leq G_i$, then $G'_i$ also has at least 2 nontrivial orbits on $\Delta_i+1$.

First suppose that $G = \bigcup_{i \in \mathbb{N}} G_i$ has linear natural orbit growth. Then, applying Theorem 3.19, it follows that $\nu = \nu_r$ is the stabilizer distribution of the ergodic action $G \acts (\Delta^r, m^{\otimes r})$ for some $r \geq 1$, where $G \acts (\Delta, m)$ is the canonical ergodic action. By Proposition 3.20, $G_2$ is self-normalizing for $m^{\otimes r}$-a.e. $\bar{x} \in \Delta^r$, and this implies that $G_2$ is self-normalizing for $\mu$-a.e. $z \in Z$. Applying Vershik [18], it follows that $\chi$ is indecomposable.
Hence we can suppose that $G = \bigcup_{i \in \mathbb{N}} G_i$ has sublinear natural orbit growth. For each $\ell \in \mathbb{N}$, define the subsets $\Delta^\ell_j \subseteq \Delta_j$ and subgroups $G(\ell)_j = \text{Alt}(\Delta^\ell_j)$ for $j \geq \ell$ inductively as follows:

- $\Delta^\ell_0 = \Delta_0$;
- $\Delta^\ell_{j+1} = \Delta_{j+1} \setminus \text{Fix}_{\Delta_{j+1}}(G(\ell)_j)$.

Since $G(\ell)_j$ has at least 2 nontrivial orbits on $\Delta_{j+1}$, it follows that each $G(\ell)_j$ is strictly contained in $G(\ell)_{j+1}$. Let $G(\ell) = \bigcup_{0 \leq j \in \mathbb{N}} G(\ell)_j$. Then it is easily checked that if $\ell < m$, then $G(\ell) \leq G(m)$ and that $G = \bigcup_{\ell \in \mathbb{N}} G(\ell)$.

**Claim 3.22.** $G(\ell)$ has linear natural orbit growth for all $\ell \in \mathbb{N}$.

**Proof.** For each $i \geq \ell$, let $n^\ell_i = |\Delta^\ell_i|$ and let $s^\ell_{i+1}$ be the number of natural $G(\ell)_i$-orbits on $\Delta^\ell_{i+1}$. Then clearly $s^\ell_{i+1} \geq s_{i+1}$ and

$$n^\ell_i \leq s^\ell_{i+1} n^\ell_i + \sum_{k=i+1}^j s^\ell_{k+1} e_k = s^\ell_i n^\ell_i + s^\ell_0 \sum_{k=i+1}^j e_k/s^\ell_0.$$

Since $s^\ell_0 \geq s_0$, it follows that

$$n^\ell_i \leq s^\ell_i n^\ell_i + s^\ell_0 \sum_{k=i}^{j} e_k/s^\ell_0 \leq s^\ell_i n^\ell_i + s^\ell_0 \tau = s^\ell_i (n^\ell_i/s^\ell_0 \tau).$$

Thus $n^\ell_i/s^\ell_i \leq n^\ell_i + s^\ell_0 \tau$ and it follows that $\lim_{j \to \infty} s^\ell_{ij}/n^\ell_i > 0$. \qed

In particular, it follows that each $G(\ell)$ is a proper subgroup of $G$. For each $\ell \in \mathbb{N}$, let $\nu(\ell)$ be the canonical ergodic action and let $m_{\ell}^\nu$ be the stabilizer distribution of $G(\ell) \cap (\Delta^\ell, m_{\ell}^\nu)$. Let $\nu_G(\ell)$ be the IRS of $G(\ell)$ arising from the $G(\ell)$-equivariant map $\text{Sub}_G \to \text{Sub}_{G(\ell)}$ defined by $H \mapsto H \cap G(\ell)$. Then Theorem 3.19 implies that there exist $\alpha(\ell), \beta(\ell), \gamma(\ell), r \in [0, 1]$ with $\alpha(\ell) + \beta(\ell) + \sum_{r \in \mathbb{N}^+} \gamma(\ell)_r = 1$ such that

$$\nu_G(\ell) = \alpha(\ell) \delta_1 + \beta(\ell) \delta_G(\ell) + \sum_{r \in \mathbb{N}^+} \gamma(\ell)_r \nu(\ell)_r.$$  

Recall that $\nu \neq \delta_1, \delta_G$. Thus (3.3), together with Proposition 3.20, implies that for $\nu$-a.e. $H \in \text{Sub}_G$, there exists an integer $\ell_H$ such that $H \cap G(\ell)$ is a (proper) self-normalizing subgroup of $G(\ell)$ for all $\ell \geq \ell_H$, and this implies that $H$ is a self-normalizing subgroup of $G$. It follows that $G_z$ is self-normalizing for $\mu$-a.e. $z \in Z$; and applying Vershik [18] once again, this implies that $\chi$ is indecomposable. \qed

For later use, we record the following recognition theorem, which will play a key role in the proofs of Theorems 3.7 and 3.19.

**Theorem 3.23.** Suppose that $G = \bigcup_{i \in \mathbb{N}} G_i$ has linear natural orbit growth and that $\nu$ is an ergodic IRS of $G$. If there exists a constant $s \geq 1$ such that for $\nu$-a.e. $H \in \text{Sub}_G$, for all but finitely many $i \in \mathbb{N}$, there exists an integer $1 \leq r_i \leq s$...
Proof. Recall that $\Delta_{i+1} = (\Delta_i \times s_{i+1}) \cup \{ \alpha_i^{i+1} | 0 \leq \ell < t_{i+1} \}$. For each $i < j$, let
$$\Phi_{ij} = \Delta_i \times s_{i+1} \times \cdots \times s_j.$$Thus $\Phi_{ij}$ is the union of the “obvious” natural $G_i$-orbits on $\Delta_j$. For each $i \in \mathbb{N}$ and $1 \leq t \leq s$, let $p_{it}$ be the $\nu$-probability that there exists $\Sigma_i \in [\Delta_i]^t$ such that $H_t = \text{Alt}(\Delta_i \setminus \Sigma_i)$. By Lemma 3.15, since $G$ has linear natural orbit growth, we have that $\lim_{j \to \infty} b_j = 0$, where
$$b_j = \lim_{k \to \infty} \frac{(n_k - s_j n_j)}{n_k}.$$It follows that for all $i \in \mathbb{N}$, if $j > i$ is sufficiently large, then $b_j$ is sufficiently small so that there exists $k > j$ such that
$$\sum_{t=1}^{t=s} p_{ktt} \left[ 1 - \frac{(s_j n_j)}{(m_{k+1})} \right] \leq \left( \frac{1}{2} \right)^{i+1}.$$Hence we can inductively define a sequence of integers $k_i$ such that
$$\sum_{t=1}^{t=s} p_{k_{i+1}t} \left[ 1 - \frac{(s_j n_j)}{(m_{k_{i+1}})} \right] \leq \left( \frac{1}{2} \right)^{i+1}.$$Applying the Borel-Cantelli Lemma, it follows that for $\nu$-a.e. $H \in \text{Sub}_G$, for all but finitely many $i \in \mathbb{N}$, there exists a subset $\Sigma_{k_{i+1}} \subseteq \Phi_{k_{i+1}i+1}$ of cardinality $r_{k_{i+1}}$ such that $H_{k_{i+1}} = \text{Alt}(\Delta_{k_{i+1}} \setminus \Sigma_{k_{i+1}})$. Furthermore, by ergodicity, there exists a constant $1 \leq r \leq s$ such that $r = \liminf r_{k_i}$ for $\nu$-a.e. $H \in \text{Sub}_G$. Suppose that $H \in \text{Sub}_G$ is such a $\nu$-generic subgroup and that $\Sigma_{k_{i+1}} \subseteq \Phi_{k_{i+1}i+1}$ is a subset of cardinality $r_{k_{i+1}} = r$ such that $H_{k_{i+1}} = \text{Alt}(\Delta_{k_{i+1}} \setminus \Sigma_{k_{i+1}})$. Using the fact that $\Sigma_{k_{i+1}} \subseteq \Phi_{k_{i+1}i+1}$ is contained in the union of the natural $G_{k_i}$-orbits on $\Delta_{k_{i+1}}$, it follows that there exists a subset $\Sigma_k \subseteq \Delta_k$ such that $r_k \leq |\Sigma_k| \leq |\Sigma_{k_{i+1}}| = r$ and $\text{Alt}(\Delta_k \setminus \Sigma_k) \leq H_k$. Consequently, it follows that $k_i = r$ for all but finitely many $i \in \mathbb{N}$.

Let $S_r$ be the standard Borel space of subgroups $H \leq G$ such that for all but finitely many $i \in \mathbb{N}$, there is a subset $\Sigma_{k_i} \in [\Delta_{k_i}]^*$ such that $H_{k_i} = \text{Alt}(\Delta_{k_i} \setminus \Sigma_{k_i})$. Then we have shown that the ergodic IRS $\nu$ concentrates on $S_r$. Since the stabilizer distribution $\nu$, of $G \curvearrowright (\Delta^*, m^{\otimes t})$ also concentrates on $S_r$, the following claim completes the proof of Theorem 3.23.

Claim 3.24. The action $G \curvearrowright S_r$ is uniquely ergodic.

(The following argument is essentially identical to the proof of Thomas-Tucker-Drob [16, Proposition 6.8].) In order to prove Claim 3.24, it is enough to show that if $\mu$ is an ergodic probability measure on $S_r$ and $B \subseteq \text{Sub}_G$ is a basic clopen subset, then $\mu(B) = \nu_r(B)$. Let $B = \{ H \in \text{Sub}_G | H \cap G_\ell = L \}$, where $\ell \in \mathbb{N}$ and $L \leq G_\ell$ is a subgroup. By the Pointwise Ergodic Theorem, there exists $H \in S_r$ such that
$$\mu(B) = \lim_{i \to \infty} | \{ g \in G_i | ghg^{-1} \in B \} | / |G_i|$$
$$= \lim_{i \to \infty} | \{ g \in G_i | ghg^{-1} \cap G_\ell = L \} | / |G_i|$$
$$= \lim_{i \to \infty} | \{ g \in G_{k_i} | gh_{k_i}g^{-1} \cap G_\ell = L \} | / |G_{k_i}|.$$
where $H_i = H \cap G_i$. Similarly, there exists $H' \in S_t$ such that
\[
\nu_{\varepsilon}(B) = \lim_{i \to \infty} \frac{| \{ g \in G_{k_i} \mid gH_{k_i}g^{-1} \cap G_\ell = L \} |}{|G_{k_i}|},
\]
where $H' = H' \cap G_i$. Since $H, H' \in S_r$, there exists $i_0 \in \mathbb{N}$ such that $H_{k_i}$ and $H'_{k_i}$ are conjugate in $G_{k_i}$ for all $i \geq i_0$ and this implies that
\[
\lim_{i \to \infty} \frac{| \{ g \in G_{k_i} \mid gH_{k_i}g^{-1} \cap G_\ell = L \} |}{|G_{k_i}|} = \lim_{i \to \infty} \frac{| \{ g \in G_{k_i} \mid gH_{k_i}g^{-1} \cap G_\ell = L \} |}{|G_{k_i}|}.
\]

Finally, recall that if $G$ is a countable group and $\chi \in F(G)$ is a character, then the corresponding proper 2-sided ideal $I_\chi$ of the group ring $CG$ is defined by
\[
I_\chi = \{ x \in C(G) \mid \chi(gx) = 0 \text{ for all } g \in G \}.
\]
As explained in Section 1, the following result exhibits a counterexample to Zalesski\i [22, Conjecture 1.24] and also answers Zalesski\i [22, Question 5.12].

**Proposition 3.25.** There exists an $L(\text{Alt})$-group $G$ such that:

(i) The augmentation ideal $\omega(CG)$ is the only nontrivial proper 2-sided ideal of $CG$.

(ii) $G$ has infinitely many nontrivial ergodic IRSs.

(iii) $G$ has infinitely many indecomposable characters $\chi$ such that $I_\chi = \{ 0 \}$.

**Proof.** Define $G_i = \text{Alt}(\Delta_i)$ and $s_{i+1}$ inductively as follows.

- $\Delta_0 = \{ 0, 1, 2, 3, 4 \}$;
- $\Delta_{i+1} = \{ \sigma^k \mid \sigma \in \Delta_i, 0 \leq k < s_{i+1} \} \cup G_i$, where $s_{i+1} = 2^i |G_i|$;

and the embedding $\varphi_i : \text{Alt}(\Delta_i) \to \text{Alt}(\Delta_{i+1})$ is defined by

- $\varphi_i(g)(\sigma^k) = g(\sigma)^{-k}$ for each $\sigma \in \Delta_i$ and $0 \leq k < s_{i+1}$;
- $\varphi_i(g)(h) = gh$ for each $h \in G_i$.

Let $G = \bigcup_{i \in \mathbb{N}} G_i$. By construction, if $i < j$, then $G_i$ has a regular orbit on $\Delta_j$. Hence, by Zalesski\i [21, Lemma 10], the augmentation ideal is the only nontrivial proper 2-sided ideal of $CG$. Also $s_{i+1}$ is clearly the number of natural orbits of $G_i$ on $\Delta_{i+1}$. Furthermore, an easy induction shows that if $i < j$, then
\[
|\Delta_j| = s_{ij}|\Delta_i| + \sum_{k=i}^{j-2} s_{k+1}s_{ij}|G_k| + |G_{j-1}|
\]
and hence
\[
\frac{n_j}{s_{ij}} = \frac{|\Delta_j|}{s_{ij}} + \sum_{k=i}^{j-2} \frac{s_{k+1}s_{ij}|G_k|}{s_{ij}} + \frac{|G_{j-1}|}{s_{ij}} 
\leq |\Delta_i| + \sum_{k=i}^{j-1} \frac{|G_k|}{s_{k+1}} 
= |\Delta_i| + \sum_{k=i}^{j-1} \frac{1}{2^k} < |\Delta_i| + 2.
\]
It follows that \( a_i = \lim_{i \to \infty} s_{ij}/n_j > 0 \) and thus \( G \) has linear natural orbit growth. Let \( G \curvearrowright (\Delta, \mu) \) be the canonical ergodic action. Then for each \( r \geq 1 \),
\[
\chi_r(g) = m^\otimes r(\text{Fix}_{\Delta^r}(g))
\]
is an indecomposable character of \( G \); and it is easily checked that if \( r \neq s \), then \( \chi_r \neq \chi_s \). Since \( \chi_r \neq \chi_\text{con} \), it follows that \( I_{\chi_r} \neq \omega(CG) \) and so \( I_{\chi_r} = \{0\} \). \( \square \)

4. Sublinear natural orbit growth

In this section, we will discuss the ergodic IRSs of the almost diagonal limits \( G = \bigcup_{i \in \mathbb{N}} G_i \) with sublinear natural orbit growth. Examining the list of the ergodic IRSs in the statement of Theorem 3.19, we see that if \( G = \bigcup_{i \in \mathbb{N}} G_i \) has linear natural orbit growth and \( \nu \neq \delta_1, \delta_G \) is an ergodic IRS, then \( \nu \) concentrates on the subspace of subgroups \( H \in \text{Sub}_G \) such that there exists a \textit{fixed} integer \( r \geq 1 \) such that for all but finitely many \( i \in \mathbb{N} \), there exists a subset \( \Sigma_i \subseteq \Delta_i \) of cardinality \( r \) such that:

- \( H \cap G_i = \text{Alt}(\Delta_i \setminus \Sigma_i) \); and
- \( \Sigma_{i+1} \) is contained in the union of the natural \( G_i \)-orbits on \( \Delta_i \).

As is suggested by the proof of Theorem 3.21, a similar result holds if \( G = \bigcup_{i \in \mathbb{N}} G_i \) is an almost diagonal limit with sublinear natural orbit growth, except that in this case:

- \( d_i = |\Sigma_i| \to \infty \) as \( i \to \infty \); and
- \( \Sigma_{i+1} \) is contained in the union of the natural and trivial \( G_i \)-orbits on \( \Delta_{i+1} \).

In order to simplify the notation, we will work with the \( G \)-invariant probability measures on the space of corresponding sequences of subsets \( (\Sigma_i) \) rather than directly with the IRSs on \( \text{Sub}_G \). Of course, such a measure can be identified with a corresponding IRS via the map

\[
\sigma = (\Sigma_i) \mapsto H(\sigma) = \bigcup \text{Alt}(\Delta_i \setminus \Sigma_i).
\]

Throughout this section, we will suppose that \( G = \bigcup_{i \in \mathbb{N}} G_i \) is an almost diagonal limit of the finite alternating groups \( G_i = \text{Alt}(\Delta_i) \). Let \( \tau = \sum_{i=1}^\infty e_i/s_{0i} < \infty \). Initially we will not assume that \( G = \bigcup_{i \in \mathbb{N}} G_i \) has sublinear natural orbit growth. Let \( \Sigma \) consist of the infinite sequences of sets \( (\Sigma_i)_{i \geq i_0} \) for some \( i_0 \in \mathbb{N} \) such that the following conditions are satisfied for all \( i \geq i_0 \):

- \( \Sigma_i \subseteq \Delta_i \);
- \( \text{Alt}(\Delta_{i+1} \setminus \Sigma_{i+1}) \cap G_i = \text{Alt}(\Delta_i \setminus \Sigma_i) \);
- \( \Sigma_{i+1} \) is contained in the union of the natural and trivial \( G_i \)-orbits on \( \Delta_{i+1} \);
- if \( i_0 > 0 \), then \( \Sigma_{i_0} \) is not contained in the union of the natural and trivial \( G_{i_0-1} \)-(orbits on \( \Delta_{i_0} \).

Then the natural action of \( G \) on \( \Sigma \) corresponds to the conjugacy action of \( G \) on the subspace of subgroups \( \{\bigcup_{i \geq i_0} \text{Alt}(\Delta_i \setminus \Sigma_i) \mid (\Sigma_i)_{i \geq i_0} \in \Sigma\} \).

**Remark 4.1.** For later use, note that if \( (\Sigma_i)_{i \geq i_0} \in \Sigma \) and \( i_0 \leq i < j \), then \( |\Sigma_i| \leq |\Sigma_j| \); and if \( |\Sigma_i| = |\Sigma_j| \), then \( \Sigma_j \) is contained in the union of the natural \( G_i \)-orbits on \( \Delta_j \).

Fix some \( \beta \in (0, \infty) \). Let \( \beta_0 = \beta \) and let \( \gamma_0 = \beta_0 \tau = \beta_0 \sum_{i=1}^\infty e_i/s_{0i} \). For each \( i \in \mathbb{N} \), let

- \( \beta_{i+1} = \beta_i/s_{i+1} = \beta_0/s_{0i+1} \); and
- \( \gamma_{i+1} = \gamma_i - \beta_i e_{i+1}/s_{i+1} = \beta_0 \sum_{j=i+2}^\infty e_j/s_{0j} \).
For each \( i \in \mathbb{N} \) and \( X \subseteq \Delta_i \), let \( \Sigma(X) \) be the set of sequences \( (\Sigma_j)_{j \geq j_0} \in \Sigma \) for some \( j_0 \leq i \) such that \( \Sigma_i = X \). Then the sets \( \Sigma(X) \) form a clopen basis for a locally compact topology on \( \Sigma \). First define \( \mu_\beta \) on the basic clopen sets by

\[
\mu_\beta(\Sigma(X)) = \frac{1}{e^{\beta_i n_i + \gamma_i}} (e^{\beta_i} - 1)^{|X|}.
\]

Note that (4.2) can be rewritten as:

\[
\mu_\beta(\Sigma(X)) = \frac{1}{e^{\gamma_i}} \left( 1 - \frac{1}{e^{\beta_i}} \right)^{|X|} \frac{1}{e^{\beta_i}} n_i - |X|.
\]

**Remark 4.2.** Consider the special case when \( G = \bigcup_{i \in \mathbb{N}} G_i \) is a diagonal limit. Then each \( \gamma_i = 0 \); and for each subset \( X \subseteq \Delta_i \), the \( \mu_\beta \)-probability that \( \Sigma_i = X \) is the probability of the event that \( X \) is the set of selected points given by the binomial distribution when the probability of selecting each point \( x \in \Delta_i \) is \( p_i = 1 - (1/e^{\beta_i}) \).

In the general case, it is necessary to introduce the “correction factor” \( 1/e^{\gamma_i} \).

Let \( \mathcal{A} \) be the algebra of Borel subsets of \( \Sigma \) generated by the basic clopen sets \( \Sigma(X) \). Note that if \( A \in \mathcal{A} \), then there exists \( i \in \mathbb{N} \) and \( S \subseteq \mathcal{P}(\Delta_i) \) such that either:

(a) \( A = \bigcup \{ \Sigma(X) \mid X \in S \} \) or

(b) \( A = \bigcup \{ \Sigma(X) \mid X \in S \} \cup (\Sigma \setminus B_i) \), where \( B_i = \bigcup \{ \Sigma(X) \mid X \in \mathcal{P}(\Delta_i) \} \).

We next extend \( \mu_\beta \) to the algebra \( \mathcal{A} \) by defining

\[
\mu_\beta(A) = \begin{cases} 
\sum_{X \in S} \mu_\beta(\Sigma(X)), & \text{if (a) holds;} \\
\sum_{X \in S} \mu_\beta(\Sigma(X)) + (1 - (1/e^{\gamma_i})), & \text{if (b) holds.}
\end{cases}
\]

We claim that \( \mu_\beta \) is a pre-measure on \( \mathcal{A} \). Of course, we must first check that \( \mu_\beta \) is well-defined. To see this, fix some \( i \in \mathbb{N} \) and for each \( X \subseteq \Delta_i \), let \( E_X \) be the collection of subsets \( Y \subseteq \Delta_{i+1} \) such that \( \text{Alt}(\Delta_{i+1} \setminus Y) \cap G_i = \text{Alt}(\Delta_i \setminus X) \) and \( Y \) is contained in the union of the natural and trivial \( G_i \)-orbits on \( \Delta_{i+1} \). We will prove by induction on \( \ell = |X| \) that \( \mu_\beta(\Sigma(X)) = \sum_{Y \in E_X} \mu_\beta(\Sigma(Y)) \).

First suppose that \( \ell = 0 \). Then

\[
\mu_\beta(\Sigma(\emptyset)) = \frac{1}{e^{\beta_i n_i + \gamma_i}}.
\]

Also \( Y \in E_0 \) if and only if \( Y \) is a subset of the trivial \( G_i \)-orbits on \( \Delta_{i+1} \). Thus

\[
\mu_\beta(E_0) = \frac{1}{e^{\beta_i n_i + \gamma_i}} \sum_{t=0}^{f_{i+1}} \binom{f_{i+1}}{t} (e^{\beta_i} - 1)^t.
\]

By definition, we have that

\[
\beta_i (n_{i+1} - f_{i+1}) + \gamma_{i+1} = \frac{\beta_i}{s_{i+1}} (s_i n_i + e_i) + \gamma_i = \beta_i e_i + \gamma_i = \beta_i n_i + \gamma_i.
\]

Hence the result holds when \( \ell = 0 \). Suppose inductively that the result holds for \( \ell \geq 0 \) and let \( X \subseteq \Delta_i \) with \( |X| = \ell + 1 \). Then

\[
\mu_\beta(\Sigma(X)) = \frac{1}{e^{\beta_i n_i + \gamma_i}} (e^{\beta_i} - 1)^{\ell+1}.
\]
Write \( X = X_0 \cup \{ x \} \), where \(|X_0| = \ell \). Then each \( Y \in E_X \) can be expressed uniquely as a disjoint union \( Y = Y_0 \cup Z \) such that \( Y_0 \in E_{X_0} \), \( Z \in E_{\{ x \}} \) and \( Z \) is contained in the union of the natural orbits of \( G_i \) on \( \Delta_{i+1} \). Thus

\[
\mu_\beta(E_X) = \sum_{Y_0 \in E_{X_0}} \mu_\beta(\Sigma(Y_0)) \sum_{t=1}^{s_i+1} \left( S_{i+1}^t \right) (e^{\beta i+1} - 1)^t
\]

\[
= \frac{1}{e^{\beta i} n_i + \gamma_i} (e^{\beta i} - 1)^\ell (e^{\beta i+1} s_i+1 - 1)
\]

\[
= \frac{1}{e^{\beta i} n_i + \gamma_i} (e^{\beta i} - 1)^{\ell+1}.
\]

Thus \( \mu_\beta(A) \) is well-defined if \( A = \bigcup \{ \Sigma(X) \mid X \in S \} \) for some \( S \subseteq \mathcal{P}(\Delta_i) \). Also, since

\[
\mu_\beta(B_i) = \frac{1}{e^{\beta i} n_i + \gamma_i} \sum_{\ell=0}^{n_i} \left( \frac{n_i}{\ell} \right) (e^{\beta i} - 1)^\ell = \frac{1}{e^{\gamma_i}},
\]

it follows that \( \mu_\beta(A) \) is well-defined if \( A = \bigcup \{ \Sigma(X) \mid X \in S \} \cup (\Sigma \setminus B_i) \); and it also follows that \( \mu_\beta(\Sigma) = 1 \). Finally to check that \( \mu_\beta \) is \( \sigma \)-additive, it is enough to show that for all \( i \in \mathbb{N} \),

\[
\sum_{j=1}^{\infty} \mu_\beta(B_{j+1} \setminus B_j) = \mu(\Sigma \setminus B_1) = 1 - (1/e)^{\gamma_i}.
\]

To see this, note that if \( k > i \), then

\[
\sum_{j=i}^{k} \mu_\beta(B_{j+1} \setminus B_j) = \sum_{j=i}^{k} [(1/e)^{\gamma_{j+1}} - (1/e)^{\gamma_j}] = (1/e)^{\gamma_{k+1}} - (1/e)^{\gamma_i};
\]

and since \( \gamma_{k+1} = \beta_0 \sum_{j=k+1}^{\infty} c_{j+1} s_{0j+1} / s_{0j+1} \to 0 \) as \( k \to \infty \), it follows that

\[
\sum_{j=i}^{k} \mu_\beta(B_{j+1} \setminus B_j) \to 1 - (1/e)^{\gamma_i}
\]

as \( k \to \infty \). This completes the proof that \( \mu_\beta \) is a pre-measure on \( \mathcal{A} \). Clearly \( \mu \) is \( G \)-invariant. Hence, by the Carathéodory Extension Theorem, \( \mu_\beta \) can be extended to a \( G \)-invariant probability measure \( \mu_\beta \) on \( \Sigma \).

**Theorem 4.3.** If \( G = \bigcup_{i \in \mathbb{N}} G_i \) is an almost diagonal limit of finite alternating groups and \( \beta \in (0, \infty) \), then the action \( G \rtimes (\Sigma, \mu_\beta) \) is ergodic if and only if \( G = \bigcup_{i \in \mathbb{N}} G_i \) has sublinear natural orbit growth.

We will begin with the easy direction in Theorem 4.3.

**Proposition 4.4.** If \( G = \bigcup_{i \in \mathbb{N}} G_i \) has linear natural orbit growth, then the action \( G \rtimes (\Sigma, \mu_\beta) \) is not ergodic.

**Proof.** If \( G = \bigcup_{i \in \mathbb{N}} G_i \) has linear natural orbit growth, then

\[
\lim_{i \to \infty} \beta_i n_i + \gamma_i = \lim_{i \to \infty} \beta_i \frac{n_i}{s_0 i} + \gamma_i = \frac{\beta_0}{\theta_0} > 0.
\]

Hence if \( \sigma \in \Sigma \) is the sequence with constant value \( \emptyset \) and \( X_0 = \{ \sigma \} \), then

\[
\mu_\beta(X_0) = \lim_{i \to \infty} \frac{1}{e^{\beta_i n_i + \gamma_i}} = \frac{1}{e^{\beta_0 / \theta_0}}.
\]
Since $X_0$ is a $G$-invariant Borel subset with $0 < \mu_\beta(X_0) < 1$, it follows that the action $G \curvearrowright (\Sigma, \mu_\beta)$ is not ergodic. \hfill $\square$

**Remark 4.5.** If $G = \bigcup_{i \in \mathbb{N}} G_i$ has linear natural orbit growth, then we can calculate the ergodic decomposition of the action $G \curvearrowright (\Sigma, \mu_\beta)$ as follows. Let $\lambda = \beta_0/a_0$. For each $r \geq 0$, if $X_r \subseteq \Sigma$ is the Borel subset consisting of the sequences $(\Sigma_j)_{j \geq j_0}$ such that $|\Sigma_j| = r$ for all but finitely many $j \geq j_0$, then

$$\mu_\beta(X_r) = \frac{1}{e^x \cdot r!}.$$ 

To see this, note that

$$\mu_\beta(X_1) = \lim_{j \to \infty} \frac{1}{\beta_j n_j + \gamma_j} \cdot n_j \left( e^{\frac{\beta_j n_j \lambda}{\gamma_j}} - 1 \right) = \frac{1}{e^x} \cdot \lambda,$$

and that if $r \geq 2$, then

$$\mu_\beta(X_r) = \lim_{j \to \infty} \frac{1}{\beta_j n_j + \gamma_j} \left( n_j \left( e^{\frac{\beta_j n_j \lambda}{\gamma_j}} - 1 \right) \right)^r$$

$$= \lim_{j \to \infty} \frac{1}{\beta_j n_j + \gamma_j} \left( \sum_{\ell=1}^r n_j^\ell \left( e^{\frac{\beta_j n_j \lambda}{\gamma_j}} - 1 \right) \right)^r$$

$$= \frac{1}{e^x} \cdot \lambda^r.$$ 

If we identify $\mu_\beta$ with the corresponding IRS of $G$, then $X_r$ corresponds to the IRS $\nu_r$ of Theorem 3.19. Thus, writing $\delta_G = \nu_0$, we obtain the ergodic decomposition:

$$\mu_\beta = \frac{1}{e^x} \sum_{r=0}^{\infty} \lambda^r \sigma_r.$$ 

For the remainder of this section, we will suppose that $G = \bigcup_{i \in \mathbb{N}} G_i$ has sublinear natural orbit growth. Here the analysis splits into two cases depending on whether or not $G \cong \text{Alt}(\mathbb{N})$; equivalently, on whether or not $s_{i+1} = 1$ and $c_{i+1} = 0$ for all but finitely many $i \in \mathbb{N}$. First suppose that $G \cong \text{Alt}(\mathbb{N})$. In order to simplify notation, we will suppose that $s_{i+1} = 1$ and $c_{i+1} = 0$ for all $i \in \mathbb{N}$, and we can also suppose that $G = \text{Alt}(\mathbb{N})$ and that each $\Delta_i = \{0, 1, \cdots, n_i - 1\}$. Let $\alpha_0 = 1 - (1/e^x)$ and $\alpha_1 = 1/e^x$. Let $p_\alpha$ be the probability measure on $\{0, 1\}$ defined by $p_\alpha(\ell) = \alpha_\ell$ and let $\mu_\alpha$ be the corresponding product probability measure on $2^\mathbb{N}$. Then $\text{Alt}(\mathbb{N})$ acts ergodically on $(2^\mathbb{N}, \mu_\alpha)$ via the shift action $(g \cdot \xi)(n) = \xi(g^{-1}(n))$. Let $\xi \triangleq (\Sigma_1^\xi)_{i \geq 0}$ be the $\text{Alt}(\mathbb{N})$-equivariant map from $2^\mathbb{N}$ to $\Sigma$ defined by

$$\Sigma_1^\xi = \{ k \in \Delta_i \mid \xi(k) = 0 \}.$$ 

Then $\mu_\beta = (f_\alpha)_* \mu_\alpha$ and it follows that the action $\text{Alt}(\mathbb{N}) \curvearrowright (\Sigma, \mu_\beta)$ is ergodic. (Using the notation of Section 9, the stabilizer distribution corresponding to $\mu_\beta$ is the ergodic IRS $\nu_{r0}$ of $\text{Alt}(\mathbb{N})$.)

Thus we can suppose that $G \cong \text{Alt}(\mathbb{N})$ and hence that $\lim_{i \to \infty} \beta_i = 0$. In order to prove that $G \curvearrowright (\Sigma, \mu_\beta)$ is ergodic, it is enough to find a $G$-invariant Borel subset $\Sigma_\beta \subseteq \Sigma$ such that $\mu_\beta(\Sigma_\beta) = 1$ and such that if $m$ is an ergodic probability measure on $\Sigma_\beta$, then

$$m(\Sigma(X) \cap \Sigma_\beta) = \mu_\beta(\Sigma(X)).$$

for all $X \in \bigcup_{i \in \mathbb{N}} \mathcal{P}(\Delta_i)$. The definition of $\Sigma_\beta$ will involve the following sequence of random variables.
Definition 4.6. For each $i \in \mathbb{N}$, let $d_i$ be the random variable on $\Sigma$ defined by

$$d_i((\Sigma_j)_{j \geq j_0}) = \begin{cases} \lfloor \Sigma_i \rfloor, & \text{if } i \geq j_0; \\ 0, & \text{otherwise.} \end{cases}$$

In preparation for an application of Chebyshev's inequality, we will next compute the expectation $E[d_i]$ and the variance $\text{Var}(d_i)$ of the random variable $d_i$. Here we will make use of the observation that modulo the “correction factor” $1/e^{\gamma_i}$, the probability that $\Sigma_i = X$ is that given by the binomial distribution when the probability of selecting each point $x \in \Delta_i$ is $p_i = 1 - (1/e^{\beta_i})$.

Lemma 4.7. $E[d_i] = e^{-\gamma_i}(1 - e^{-\beta_i})n_i$.

Proof. Using equation (4.3), we see that

$$E[d_i] = e^{-\gamma_i}n_ip_i = e^{-\gamma_i}(1 - e^{-\beta_i})n_i.$$  

□

Lemma 4.8. $\text{Var}(d_i) = (e^{\gamma_i} - 1)E[d_i]^2 + e^{-\beta_i}E[d_i]$.

Proof. Again using equation (4.3), we see that

$$E[d_i^2] = e^{-\gamma_i}[n_ip_i + n_i(n_i - 1)p_i^2]$$

and a routine computation shows that

$$\text{Var}(d_i) = E[d_i^2] - E[d_i]^2 = (e^{\gamma_i} - 1)E[d_i]^2 + e^{-\beta_i}E[d_i].$$  

□

Proposition 4.9. There exists an increasing sequence $I = (i_k \mid k \in \mathbb{N})$ such that $\lim_{k \to \infty} d_{i_k}/\beta_{i_k}n_{i_k} = 1$ for $\mu_\beta$-a.e. $(\Sigma_i)_{i \geq j_0} \in \Sigma$.

Proof. Since $\beta_i = \beta_0/s_{0i} \to 0$, it follows that $(1 - e^{-\beta_i})/\beta_i \to 1$. Since we also have that $\gamma_i \to 0$, it follows from Lemma 4.7 that

$$\lim_{i \to \infty} E[d_i]/\beta_in_i = 1.$$

In particular, since $G$ has sublinear natural orbit growth and

$$E[d_i] \approx \beta_in_i = \beta_0\frac{n_i}{s_{0i}},$$

it follows that $E[d_i] \to \infty$. Hence, letting $\sigma(d_i) = \sqrt{\text{Var}(d_i)}$ denote the standard deviation, applying Lemma 4.8, we see that

$$\lim_{i \to \infty} \sigma(d_i)/E[d_i] = 0.$$  

Combining (4.4) and (4.5), there exists an increasing sequence $I = (i_k \mid k \in \mathbb{N})$ such that for all $k \in \mathbb{N}$,

(a) $(1 - 1/2^k)\beta_{i_k}n_{i_k} \leq E[d_{i_k}] \leq (1 + 1/2^k)\beta_{i_k}n_{i_k}$ and
(b) $\sigma(d_{i_k}) \leq E[d_{i_k}]/4^k$.

Let $E_k$ be the event that $|d_{i_k} - E[d_{i_k}]| \geq E[d_{i_k}]/2^k$. Applying Chebyshev’s inequality, since $E[d_{i_k}]/2^k \geq 2^k\sigma(d_{i_k})$, it follows that $P(E_k) \leq 1/4^k$. Applying the Borel-Cantelli Lemma, for $\mu_\beta$-a.e. $(\Sigma_i)_{i \geq j_0} \in \Sigma$, for all but finitely many $k \in \mathbb{N}$,

$$(1 - 1/2^k)E[d_{i_k}] \leq d_{i_k} \leq (1 + 1/2^k)E[d_{i_k}]$$
and hence
\[(1 - 1/2^k) \beta_k n_k \leq d_k \leq (1 + 1/2^k) \beta_k n_k.\]

It follows that \(\lim_{k \to \infty} d_k / \beta_k n_k = 1\) for \(\mu_\beta\)-a.e. \((\Sigma_i)_{i \geq i_0} \in \Sigma\). \(\square\)

**Definition 4.10.** \(\Sigma_\beta\) is the set of \((\Sigma_i)_{i \geq i_0} \in \Sigma\) such that \(\lim_{k \to \infty} d_k / \beta_k n_k = 1\).

Since \(\mu_\beta(\Sigma_\beta) = 1\), in order to show that \(G \cap (\Sigma, \mu_\beta)\) is ergodic, it is enough to prove the following result.

**Proposition 4.11.** If \(m\) is an ergodic probability measure on \(\Sigma_\beta\), then
\[m(\Sigma(X) \cap \Sigma_\beta) = \mu_\beta(\Sigma(X))\]
for all \(X \in \bigcup_{i \in \mathbb{N}} P(\Delta_i)\).

So suppose that \(m\) is an ergodic probability measure on \(\Sigma_\beta\). Then by the Pointwise Ergodic Theorem, there exists an element \((\Sigma_k)_{k \geq k_0} \in \Sigma_\beta\) such that
\[m(\Sigma(X) \cap \Sigma_\beta) = \lim_{j \to \infty} \frac{1}{|G_j|} \left| \{ g \in G_j \mid g \cdot (\Sigma_k)_{k \geq k_0} \in \Sigma(X) \} \right|\]
for all \(X \in \bigcup_{i \in \mathbb{N}} P(\Delta_i)\). Fix some \(X \subseteq \Delta_i\). For each \(j > \max\{i, k_0\}\), let \(d_j = |\Sigma_j|\) and let
\[m_{ij} = s_{ij} n_j + \sum_{k=1}^{j-1} s_{kj} e_k + e_j\]
\[= s_{ij} n_j + s_{0j} \sum_{k=1}^{j} e_k / s_{0k}.\]

Then an easy induction on \(\ell = |X|\) shows that
\[\frac{1}{|G_j|} \left| \{ g \in G_j \mid g \cdot (\Sigma_k)_{k \geq k_0} \in \Sigma(X) \} \right| = \sum_{t=0}^{\ell} (-1)^{\ell-t} \binom{\ell}{t} \frac{(n_j - m_{ij} + ts_{ij})}{d_j n_j};\]
and a second induction using (4.6) shows that for all \(0 \leq t \leq n_i\), the limit
\[\lim_{j \to \infty} \frac{(n_j - m_{ij} + ts_{ij})}{d_j n_j}\]
extists. We will make repeated use of the following lemma in the remaining sections of this paper.

**Lemma 4.12.** Suppose that \((n_j)_{j \in \mathbb{N}}, (m_j)_{j \in \mathbb{N}}\) and \((d_j)_{j \in \mathbb{N}}\) are sequences of natural numbers such that the following conditions are satisfied:

(a) \(m_j, d_j \leq n_j\).
(b) \(m_j/n_j \to 0\) and \(d_j/n_j \to 0\) as \(j \to \infty\).
(c) \(\lim_{j \to \infty} \frac{(n_j - m_j)}{d_j} \frac{(m_j)}{n_j}\) exists.

Then \(\lim_{j \to \infty} d_j m_j/n_j\) exists and
\[\lim_{j \to \infty} \frac{(n_j - m_j)}{d_j n_j} = \left(\frac{1}{e}\right) \lim_{j \to \infty} d_j m_j/n_j.\]
Proof. In order to simply notation, we will write \( n, d, m \) instead of \( n_j, d_j, m_j \). Note that, since
\[
\binom{n-m}{d} = \frac{(n-m)(n-m-1) \ldots (n-m-d+1)}{n} \binom{n-1}{d}.
\]
it follows that
\[
\left( \frac{n-m-d+1}{n-d+1} \right) = \left( \frac{n-m}{n} \right)^d,
\]
and hence that
\[
(4.8) \quad \left( \frac{m}{n-d+1} \right)^{\frac{n-m+1}{n-d+1}} \leq \left( \frac{n-m}{n} \right)^{\frac{d}{n}} \leq \left( \frac{m}{n} \right)^{\frac{d}{n}}.
\]
Since \( \frac{m}{n} \to 0 \) and \( \frac{m}{n-d+1} \to 0 \), it follows that
\[
(4.9) \quad \left( \frac{m}{n-d+1} \right)^{\frac{n-m+1}{n-d+1}} \to \left( \frac{1}{e} \right) \quad \text{and} \quad \left( \frac{m}{n} \right)^{\frac{d}{n}} \to \left( \frac{1}{e} \right).
\]
The result follows easily. \( \square \)

We next check that Lemma 4.12 can be applied to each of the limits (4.7). First note that if \( m_j = m_{ij} - ts_{ij} \), then
\[
\frac{m_j}{n_j} = \sum_{k=1}^{j} \frac{s_{ij}(n_i - t) + s_{ij} \sum_{k=1}^{j} e_k / s_{0k}}{n_j} \leq \frac{s_{ij}(n_i - t) + s_{ij} \sum_{k=1}^{j} e_k / s_{0k}}{n_j},
\]
and since \( G \) has sublinear natural orbit growth, this implies that \( m_j/n_j \to 0 \). Also note that
\[
\lim_{k \to \infty} \frac{d_{jk}}{n_{jk}} = \lim_{k \to \infty} \frac{d_{jk}}{n_{jk}} = \lim_{k \to \infty} \frac{n_{jk}}{n_{jk}} = 0.
\]
Hence, applying Lemma 4.12, we obtain that
\[
(4.10) \quad \lim_{j \to \infty} \frac{(m_j - m_{ij} + ts_{ij})}{d_{ij}} = \left( \frac{1}{e} \right) \lim_{k \to \infty} \frac{d_{jk} (m_{ijk} - ts_{ijk})}{n_{ijk}} .
\]

**Lemma 4.13.** For all \( i \in \mathbb{N} \) and \( 0 \leq t \leq n_i \),
\[
\lim_{k \to \infty} \frac{d_{jk} (m_{ijk} - ts_{ijk})}{n_{jk}} = \beta_i (n_i - t) + \gamma_i.
\]

**Proof.** First note that since \( \beta_j ts_{ij} = t \beta_k \) and
\[
\beta_j m_{ij} = \beta_j s_{ij} n_i + \beta_j s_{ij} \sum_{k=1}^{j} e_k / s_{0k} = \beta_i n_i + \beta_0 \sum_{k=1}^{j} e_k / s_{0k},
\]
it follows that \( \lim_{j \to \infty} \beta_j (m_{ijk} - ts_{ijk}) = \beta_i (n_i - t) + \gamma_i \). Hence, using the fact that \( \lim_{k \to \infty} d_{jk} / \beta_{jk} n_{jk} = 1 \), we obtain that
\[
\lim_{k \to \infty} \frac{d_{jk} (m_{ijk} - ts_{ijk})}{n_{jk}} = \lim_{k \to \infty} \frac{d_{jk} \beta_j (m_{ijk} - ts_{ijk})}{\beta_{jk} n_{jk}} = \beta_i (n_i - t) + \gamma_i.
\]
\( \square \)
Summing up, we have shown that if \( X \subseteq \Delta_i \) with \(|X| = \ell\), then
\[
m(\Sigma(X) \cap \Sigma_\beta) = \sum_{t=0}^\ell (-1)^{\ell-t} \left( \frac{\ell}{t} \right) \frac{(n_j-m_j+t_s_i)}{d_j} \frac{1}{\ell_t}\beta_i(n_i-t)+\gamma_i \frac{1}{e} \sum_{t=0}^\ell \left( \frac{\ell}{t} \right) e^{\beta_i t} (-1)^{t-1} \frac{1}{e} \beta_i n_i + \gamma_i (e^{\beta_i} - 1)^\ell \frac{1}{e} = \mu_\beta(\Sigma(X)),
\]
as desired. This completes the proof that the action \( G \acts (\Sigma, \mu_\beta) \) is ergodic.

**Definition 4.14.** Let \( \nu_\Sigma \Sigma_\beta \) be the stabilizer distribution of the action \( G \acts (\Sigma, \mu_\beta) \).

We can now state the third main result of this paper.

**Theorem 4.15.** If \( G = \bigcup_{i \in \mathbb{N}} G_i \) is an almost diagonal limit with sublinear natural orbit growth and \( G \not\cong \text{Alt}(\mathbb{N}) \), then the ergodic IRSs of \( G \) are
\[
\{ \delta_1, \delta_G \} \cup \{ \nu_\Sigma^\beta \mid \beta \in (0, \infty) \}.
\]

In particular, if \( G = \bigcup_{i \in \mathbb{N}} G_i \) is an almost diagonal limit with sublinear natural orbit growth and \( G \not\cong \text{Alt}(\mathbb{N}) \), then the collection \( \{ \nu_\Sigma^\beta \mid \beta \in (0, \infty) \} \) is independent of the particular expression of \( G \) as an almost diagonal limit of finite alternating groups.

## 5. Groups of almost diagonal type

In Section 3, we proved that an \( L(\text{Alt}) \)-group \( G = \bigcup_{i \in \mathbb{N}} G_i \) has linear natural orbit growth if and only if there exists a \( G \)-invariant ergodic probability measure on \( \Delta \). In this section, we will prove a corresponding characterization of the almost diagonal limits of sublinear natural orbit growth.

**Theorem 5.1.** Suppose that \( G = \bigcup_{i \in \mathbb{N}} G_i \) is the union of a strictly increasing chain of finite alternating groups \( G_i = \text{Alt}(\Delta_i) \) such that \( s_{i+1} > 1 \) for all \( i \in \mathbb{N} \). Suppose also that \( G \) has sublinear natural orbit growth and that there exists a nonatomic \( G \)-invariant ergodic probability measure \( \mu \) on \( \Sigma \). Then:

(a) \( G = \bigcup_{i \in \mathbb{N}} G_i \) is an almost diagonal limit; and

(b) there exists \( \beta \in (0, \infty) \) such that \( \mu = \mu_\beta \).

**Proof.** Applying the Pointwise Ergodic Theorem, let \( (\Sigma_j)_{j \geq j_0} \in \Sigma \) be such that for all \( i \in \mathbb{N} \) and \( X \subseteq \Delta_i \),
\[
\mu(\Sigma_j(X)) = \lim_{j \to \infty} \frac{1}{|G_j|} |\{ g \in G_j \mid g \cdot (\Sigma_j)_{j \geq j_0} \in \Sigma(X) \}|.
\]
Let \(|\Sigma_j| = d_j\).

**Claim 5.2.** \( \lim_{j \to \infty} d_j = \infty \).
Proof of Claim 5.2. Suppose not. Then, by Remark 4.1, there exist integers \( d \geq 0 \) and \( j_1 \geq j_0 \) such that \( d_j = d \) for all \( j \geq j_1 \). Suppose that \( X \subseteq \Delta_i \) with \( |X| = \ell \geq 1 \) and that \( \mu(\Sigma(X)) \neq 0 \). Let \( j \geq \max\{i, j_1\} \) and let

\[ \Phi_{ij} = \Delta_i \times s_{i+1} \times \cdots \times s_j, \]

be the union of the “obvious” natural \( G_i \)-orbits on \( \Delta_j \). Then if \( g \in G_j \) satisfies \( g \cdot \Sigma_i \) satisfies \( g \cdot \Sigma_i \) satisfies \( g \cdot (\Sigma_j \cap \Phi_{ij}) \geq \ell \). Hence (5.1) implies that \( \ell \leq d \) and that

\[
\mu(\Sigma(X)) \leq \lim_{j \to \infty} \sum_{t=\ell}^{d} \left( \frac{s_{ij}n_i}{t} \right) \left( \frac{n_j - m_{ij}}{d-t} \right) = \lim_{j \to \infty} \sum_{t=\ell}^{d} \left( \frac{s_{ij}n_i}{t} \right) \left( \frac{n_j - m_{ij}}{d-t} \right) \leq \lim_{j \to \infty} \sum_{t=\ell}^{d} \left( \frac{s_{ij}n_i}{t} \right) \left( \frac{n_j - m_{ij}}{d-t} \right).
\]

Since \( G \) has sublinear natural orbit growth, it follows that if \( \ell \leq t \leq d \), then

\[
\lim_{j \to \infty} \left( \frac{s_{ij}n_i}{t} \right) \left( \frac{n_j - m_{ij}}{d-t} \right) = 0.
\]

But this implies that \( \mu(\Sigma(X)) = 0 \), which is a contradiction. Thus no such \( X \subseteq \Delta_i \) exists and it follows that \( \mu \) concentrates on the \( G \)-invariant sequence \( \sigma \in \Sigma \) with constant value \( \emptyset \), which is a contradiction.

Arguing as in Section 4, we see that if \( X \subseteq \Delta_i \) with \( |X| = \ell \), then

\[
(5.2) \quad \mu(\Sigma(X)) = \lim_{j \to \infty} \sum_{t=0}^{\ell} (-1)^{\ell-t} \binom{\ell}{t} \left( \frac{n_j - m_{ij} + ts_{ij}}{d_j} \right);
\]

and that the limit

\[
\lim_{j \to \infty} \left( \frac{n_j - m_{ij} + ts_{ij}}{d_j} \right)
\]

exists for all \( 0 \leq t \leq n_i \). We will now work towards verifying that the hypotheses of Lemma 4.12 are satisfied. For each \( 0 \leq t \leq n_i \), let \( m_{itj} = m_{ij} - ts_{ij} \).

Claim 5.3. If \( i \in \mathbb{N} \) and \( 0 \leq t \leq n_i \), then \( \lim_{j \to \infty} m_{itj}/n_j = 0 \).

Proof of Claim 5.3. Suppose that there exist integers \( i, t \) with \( 0 \leq t \leq n_i \) such that \( \lim_{j \to \infty} m_{itj}/n_j \neq 0 \). Since

\[
\frac{m_{itj}}{n_j} = (n_i - t) \frac{s_{ij}}{n_j} + \frac{s_{0j}}{n_j} j \sum_{k=i+1}^{j} c_k/s_{0k}
\]

and \( \lim_{j \to \infty} \frac{s_{ij}}{n_j} = 0 \), it follows that

\[
\lim \sup_{j \to \infty} \frac{m_{itj}}{n_j} = \lim \sup_{j \to \infty} \frac{s_{0j}}{n_j} j \sum_{k=i+1}^{j} c_k/s_{0k}.
\]
and hence there exists a constant $0 < c < 1$ such that $\limsup_{j \to \infty} m_{ij}/n_j = c$ for all $0 \leq t \leq n_i$. Note that if $t < m$, then

$$\frac{s_{0j}}{n_j} \sum_{k=t+1}^{j} e_k/s_{0k} = \frac{s_{0j}}{n_j} \sum_{k=t+1}^{m} e_k/s_{0k} + \frac{s_{0j}}{n_j} \sum_{k=m+1}^{j} e_k/s_{0k}$$

and that $\lim_{j \to \infty} \frac{s_{0j}}{n_j} \sum_{k=t+1}^{m} e_k/s_{0k} = 0$. It follows that $\limsup_{j \to \infty} m_{ij}/n_j = c$ for all integers $i, t$ with $0 \leq t \leq n_i$. Since

$$\left( \frac{m_{ij}}{n_j} \right)_{d_j} \leq \left( 1 - \frac{m_{ij}}{n_j} \right)^{d_j} \left( 1 - \frac{m_{ij}}{n_j} \right)_{d_j} \leq \left( \frac{1}{2} \right)^{c m_{ij}}$$

for all $j \in J_{it}$ such that $0 \leq t < n_i$, then

$$\lim_{j \to \infty} m_{ij} = \lim_{j \to \infty} \left( (n_i - t)s_{ij} + s_{0j} \sum_{k=t+1}^{j} e_k/s_{0k} \right) = \infty,$$

and it follows that

$$\lim_{j \to \infty} \left( \frac{m_{ij} + ts_{ij}}{n_j} \right)_{d_j} = \lim_{j \to \infty} \left( \frac{m_{ij}}{n_j} \right)_{d_j} = 0.$$
Proof of Claim 5.5. Suppose not. Then, since
\[ \tau = \sum_{i=1}^{\infty} \frac{e_i}{s_i} = \infty \]
and
\[ d_j m_{ij}/n_j = \frac{n_j d_j s_{ij}}{n_j} + \sum_{k=i+1}^{j} \frac{e_k}{s_0k} d_j s_{0j}/n_j, \]
it follows that \( \lim_{j \to \infty} d_j s_{0j}/n_j = 0 \) and hence
\[ \lambda_0_i = \lim_{j \to \infty} d_j m_{ij}/n_j = \lim_{j \to \infty} \sum_{k=i+1}^{j} \frac{e_k}{s_0k}. \]
Also notice that
\[ \lambda_0_i = \lim_{j \to \infty} \left[ \frac{d_j s_{0j}}{n_j} \left( \frac{e_i+1}{s_{0i}} + \sum_{k=i+2}^{j} \frac{e_k}{s_0k} \right) \right] \]
\[ = \lambda_{0i+1}. \]
Thus there exists a constant \( \lambda \) such that \( \lambda_0_i = \lambda \) for all \( i \in \mathbb{N} \). Next notice that if \( 0 \leq t \leq n_i \), then
\[ \lambda_{ti} = \lim_{j \to \infty} \left[ d_j m_{ij}/n_j - \frac{t}{s_{0i}} d_j s_{0j}/n_j \right] \]
\[ = \lim_{j \to \infty} d_j m_{ij}/n_j \]
\[ = \lambda. \]
Hence for all \( i \in \mathbb{N} \) and \( X \subseteq \Delta_i \), if \( |X| = \ell \), then
\[ \mu(\Sigma(X)) = \sum_{t=0}^{\ell} (-1)^{\ell-t} \binom{\ell}{t} \left( \frac{1}{\ell} \right)^{\lambda} \]
\[ = \begin{cases} (\frac{1}{\ell})^{\lambda}, & \text{if } \ell = 0; \\ 0, & \text{otherwise}. \end{cases} \]
It follows that \( \lambda = 0 \) and that \( \mu \) concentrates on the sequence \( \sigma \in \Sigma \) with constant value \( \emptyset \), which contradicts the assumption that \( \mu \) is nonatomic. \( \square \)

Summing up, we have shown that \( \tau = \sum_{i=1}^{\infty} \frac{e_i}{s_i} < \infty \) and that if \( X \subseteq \Delta_i \) with \( |X| = \ell \), then
\[ \mu(\Sigma(X)) = \lim_{j \to \infty} \sum_{t=0}^{\ell} (-1)^{\ell-t} \binom{\ell}{t} \left( \frac{n_j-m_{ij}+ts_{ij}}{d_j} \right) \left( \frac{1}{\ell} \right)^{\lambda_{ti}} \]
\[ = \lim_{j \to \infty} \sum_{t=0}^{\ell} (-1)^{\ell-t} \binom{\ell}{t} \left( \frac{1}{\ell} \right)^{\lambda_{ti}}, \]
where \( \lambda_\ell = \lim_{j \to \infty} d_j (m_{ij} - ts_{ij})/n_j \). In particular, the limit

\[
\lim_{j \to \infty} d_j m_{ij}/n_j = \lim_{j \to \infty} \left[ \frac{n_i}{s_{0i}} + \sum_{k=1}^{j} \frac{e_k/s_{0k}}{n_j} \right] \frac{d_j s_{0j}}{n_j}
\]

exists; and this implies that \( \beta = \lim_{j \to \infty} d_j s_{0j}/n_j \) exists. Furthermore, the proof of Claim 5.5 shows that \( \beta \neq 0 \). Notice that

\[
\lambda_\ell = \lim_{j \to \infty} d_j \left[ (n_i - t)s_{ij} + s_{0j} \sum_{k=1}^{j} e_k/s_{0k} \right]/n_j
\]

\[
= \lim_{j \to \infty} \left[ \frac{1}{s_{0i}} d_j s_{0j} (n_i - t) + \frac{d_j s_{0j}}{n_j} \sum_{k=1}^{j} \frac{e_k/s_{0k}}{n_j} \right]
\]

\[
= \frac{1}{s_{0i}} \beta (n_i - t) + \beta \sum_{k=1}^{\infty} e_k/s_{0k}
\]

\[
= \beta_i (n_i - t) + \gamma_i,
\]

where \( \beta_i = \beta/s_{0i} \) and \( \gamma_i = \beta \sum_{k=1}^{\infty} e_k/s_{0k} \). It follows that if \( X \subseteq \Delta_i \) with \( |X| = \ell \), then

\[
\mu(\Sigma(X)) = \frac{1}{e^{\beta_i + \gamma_i}} \left( e^{\beta_i} - 1 \right)^\ell.
\]

Thus \( \mu = \mu_\beta \). This completes the proof of Theorem 5.1.

**Remark 5.6.** Examining the proofs of Proposition 4.11 and Theorem 5.1, we see that if \( \beta \in (0, \infty) \) and \( (\Sigma_j)_{j \geq j_0} \in \Sigma \) with \( |\Sigma_j| = d_j \), then the following are equivalent:

(a) \( \lim_{j \to \infty} d_j s_{0j}/n_j = \beta \).

(b) For all \( i \in \mathbb{N} \) and \( X \subseteq \Delta_i \),

\[
\mu(\Sigma(X)) = \lim_{j \to \infty} \frac{1}{|G_j|} \{|g \in G_j | g \cdot (\Sigma_j)_{j \geq j_0} \in \Sigma(X) \}|.
\]

We have already noted that Theorem 4.15 implies if \( G = \bigcup_{i \in \mathbb{N}} G_i \) is an almost diagonal limit with sublinear natural orbit growth and \( G \not\cong \text{Alt}(\mathbb{N}) \), then the collection \( \{ \nu_\beta^\Sigma \beta | \beta \in (0, \infty) \} \) is independent of the particular expression of \( G \) as an almost diagonal limit of finite alternating groups. The following special case will play a key role in the proof of Theorem 4.15.

**Theorem 5.7.** Suppose that \( G = \bigcup_{i \in \mathbb{N}} G_i \) is an almost diagonal limit of finite alternating groups \( G_i = \text{Alt}(\Delta_i) \). Let \( (k_i | i \in \mathbb{N}) \) be a strictly increasing sequence of natural numbers, let \( \Delta'_i = \Delta_{k_i} \) and let \( \Sigma' \) be the associated space of sequences \( (\Sigma'_i)_{i \geq i_0} \). Then \( G = \bigcup_{i \in \mathbb{N}} G'_i \) is also an almost diagonal limit and there exists a positive \( \lambda' \) such that \( \nu_{\beta}^{\Sigma} = \nu_{\lambda'}^{\Sigma'} \) for all \( \beta \in (0, \infty) \). Consequently, we have that

\[
\{ \nu_{\beta}^{\Sigma} | \beta \in (0, \infty) \} = \{ \nu_{\beta'}^{\Sigma'} | \beta' \in (0, \infty) \}.
\]

**Proof.** Of course, by Proposition 3.4, we already know that \( G = \bigcup_{i \in \mathbb{N}} G'_i \) is an almost diagonal limit.

Let \( \sigma = (\Sigma_j)_{j \geq j_0} \in \Sigma \) and let \( i_1 = \min \{ i | k_i \geq j_0 \} \). Then a moment’s thought shows that if \( i \geq i_1 \), then \( \Sigma_{k_i+1} \) is contained in the union of the natural and trivial
the values of the normalized permutation characters of various actions $\text{Alt}(\Delta)$. Thus there exists a unique $\sigma' = (\Sigma'_{j})_{j \geq i_{0}} \in \Sigma'$ such that $i_{0} \leq i_{1}$ and $\Sigma'_{i} = \Sigma_{k_{i}}$ for all $i \geq i_{1}$. Furthermore, it is clear that

$$H(\sigma) = \bigcup \text{Alt}(\Delta_{j} \setminus \Sigma_{j}) = \bigcup \text{Alt}(\Delta'_{j} \setminus \Sigma'_{j}) = H(\sigma').$$

Thus for every nonatomic $G$-invariant ergodic probability measure $\mu$ on $\Sigma$, there exists a nonatomic $G$-invariant ergodic probability measure $\mu'$ on $\Sigma'$ such that the corresponding stabilizer distributions coincide. Applying Theorem 5.1(b) to $G = \bigcup_{i \in \mathbb{N}} G'_{i}$ and $\Sigma'$, it follows that for every $\beta \in (0, \infty)$, there exists $\beta' \in (0, \infty)$ such that $\nu_{\beta}^{G} = \nu_{\beta'}^{G'}$.

Let $n'_{i}, s'_{i}$ be the parameters associated with the union $G = \bigcup_{i \in \mathbb{N}} G'_{i}$ and suppose that $\beta, \beta' \in (0, \infty)$ are such that $\nu_{\beta}^{G} = \nu_{\beta'}^{G'}$. Then the Pointwise Ergodic Theorem and Remark 5.6 imply that there exist corresponding sequences $\sigma = (\Sigma_{j})_{j \geq i_{0}} \in \Sigma$ and $\sigma' = (\Sigma'_{j})_{j \geq i_{0}} \in \Sigma'$ such that:

- $\Sigma'_{j} = \Sigma_{k_{j}}$ for all but finitely many $i \in \mathbb{N}$,
- $\lim_{j \to \infty} |\Sigma_{j}| s_{0j} / n_{j} = \beta$, and
- $\lim_{i \to \infty} |\Sigma'_{j}| s'_{0j} / n'_{j} = \beta'$.

It follows that

$$\lambda = \frac{\beta'}{\beta} = \lim_{i \to \infty} \frac{|\Sigma'_{j}| s'_{0j} / n'_{j} |}{|\Sigma_{j}| s_{0j} / n_{j}} = \lim_{i \to \infty} \frac{s'_{0j}}{s_{0j}},$$

is independent of the choice of $\beta$. \hfill $\square$

6. Normalized permutation characters of finite alternating groups

In this section, we will present a series of lemmas concerning upper bounds for the values of the normalized permutation characters of various actions $\text{Alt}(\Delta) \cap \Omega$ of the finite alternating group $\text{Alt}(\Delta)$ on a finite set $\Omega$. No attempt will be made to prove the best possible results: we will be content to prove easy results which are good enough to serve our purposes in this paper.

Suppose that $G = \bigcup_{i \in \mathbb{N}} G_{i}$ has linear natural orbit growth. Let $\nu \neq \delta_{1}, \delta_{G}$ be an ergodic IRS of $G$. Then, applying Kreutz-Peterson [2, Proposition 3.3.1], we can suppose that $\nu$ is the stabilizer distribution of an ergodic action $G \curvearrowright (Z, \mu)$. Let $\chi(g) = \mu(\text{Fix}_Z(g))$ be the corresponding character. For each $z \in Z$ and $i \in \mathbb{N}$, let $\Omega_{i}(z) = \{ g \cdot z \mid g \in G_{i} \}$. Then, by Theorem 2.1, for $\mu$-a.e. $z \in Z$, for all $g \in G$, we have that

$$\mu(\text{Fix}_Z(g)) = \lim_{i \to \infty} |\text{Fix}_{\Omega_{i}(z)}(g)| / |\Omega_{i}(z)|.$$  

Fix such an element $z \in Z$ and let $H = \{ h \in G \mid h \cdot z = z \}$ be the corresponding point stabilizer. Clearly we can suppose that $z$ has been chosen such that if $g \in H$, then $\chi(g) > 0$.

For each $i \in \mathbb{N}$, let $H_{i} = H \cap G_{i}$. Then, examining the list of ergodic IRSs in the statement of Theorem 3.19, we see that it is necessary to show that there exists a fixed integer $r \geq 1$ such that for all but finitely many $i \in \mathbb{N}$, there is a subset $\Sigma_{i} \subseteq \Delta_{i}$ of cardinality $r$ such that $H_{i} = \text{Alt}(\Delta_{i} \setminus \Sigma_{i})$. We will eventually show that if this is not the case, then there exists an element $g \in H$ such that

$$\mu(\text{Fix}_Z(g)) = \lim_{i \to \infty} |gH_{i} \cap H_{i}| / |gH_{i}| = |\{ s \in G_{i} \mid sgs^{-1} \in H_{i} \}| / |G_{i}| = 0,$$

which is a contradiction. For example, Lemma 6.1 will play a key role in the proof that there do not exist infinitely many $i \in \mathbb{N}$ such that $H_{i}$ acts primitively on $\Delta_{i}$.
and Lemmas 6.3 and 6.5 will play key roles in the proof that there do not exist infinitely many \( i \in \mathbb{N} \) such that \( H_i \) acts imprimitively on \( \Omega \).

For the remainder of this section, let \( \Delta = \{ 1, 2, \cdots, n \} \).

**Lemma 6.1.** For each prime \( p \) and real number \( a > 0 \), there exists \( n_{p,a} \in \mathbb{N} \) such that if \( n \geq n_{p,a} \) and

(i) \( g \in \text{Alt}(\Delta) \) is a product of \( b \geq p \)-cycles;

(ii) \( K < \text{Alt}(\Delta) \) is a proper primitive subgroup;

then the normalized permutation character of the action \( \text{Alt}(\Delta) \rhd \Omega = \text{Alt}(\Delta)/K \) satisfies

\[ |g^{\text{Alt}(\Delta)})|/|\Omega| < \frac{n!}{p!b!(n-bp)!}. \]

Proof. Clearly we can suppose that \( n \) has been chosen so that \( b \geq an \geq 2 \). In particular, since \( g \) contains at least two \( p \)-cycles, this implies that the conjugacy classes of \( g \) in \( \text{Alt}(\Delta) \) and \( \text{Sym}(\Delta) \) coincide and hence

\[ |g^{\text{Alt}(\Delta)})| < \frac{n!}{p!b!(n-bp)!}. \]

Applying Stirling’s Approximation and the fact that \( b \geq an \), it follows that there exist constants \( r, s \) such that

\[ |g^{\text{Alt}(\Delta)})| > rs^n \frac{n^n}{\beta^{(n-bp)}n^{n-bp}} > rs^n \frac{n^n}{n^n n^{-b}} \geq r s^n (n^n)^{(p-1)a}. \]

By Praeger-Saxl [12], since \( K \) is a proper primitive subgroup of \( \text{Alt}(\Delta) \), it follows that \( |K| < 4^n \). By Proposition 2.2, this implies that

\[ |\text{Fix}_\Omega(g)|/|\Omega| \leq |g^{\text{Alt}(\Delta)} \cap K|/|K| \leq |g^{\text{Alt}(\Delta)})| \leq \frac{4^n}{r s^n (n^n)^{(p-1)a}}. \]

The result follows easily. \( \square \)

**Lemma 6.2.** Let \( \Omega = [\Delta]^\ell \) be the set of \( \ell \)-subsets of \( \Delta \) for some \( 2 \leq \ell \leq n/2 \). Suppose that \( g \in \text{Alt}(\Delta) \) has prime order \( p > 2 \) and that \( c = |\text{Fix}_\Delta(g)| \leq n/4 \). Then the normalized permutation character of the action \( \text{Alt}(\Delta) \rhd \Omega \) satisfies:

(i) \( |\text{Fix}_\Omega(g)|/|\Omega| < \frac{c}{2}|\text{Fix}_\Delta(g)|/|\Delta| \) if \( c \geq 16 \);

(ii) \( |\text{Fix}_\Omega(g)|/|\Omega| < \frac{n}{2} \) if \( c < 16 \).

Proof. First suppose that \( \ell < p \). Then \( \text{Fix}_\Omega(g) = |\text{Fix}_\Delta(g)|^\ell \). Clearly we can suppose that \( c \geq \ell \) and since \( c \leq n/4 \), it follows that

\[ |\text{Fix}_\Omega(g)|/|\Omega| = \binom{\ell}{c} \leq \frac{c(c-1)\cdots(c-\ell)}{n(n-1)\cdots(n-\ell-1)} \leq \frac{c(c-1)}{n(n-1)} < \frac{c}{4n} \leq \frac{|\text{Fix}_\Delta(g)|}{2|\Delta|}. \]

Next suppose that \( \ell \geq p > 2 \). Let \( \mathcal{A} = \{ S \in \text{Fix}_\Omega(g) \mid S \subseteq \text{Fix}_\Delta(g) \} \) and let \( \mathcal{B} = \text{Fix}_\Omega(g) \setminus \mathcal{A} \). If \( \mathcal{A} \neq \emptyset \), then

\[ |\mathcal{A}|/|\Omega| = \binom{\ell}{c} \leq \frac{c(c-1)(c-2)}{n(n-1)(n-2)} < \frac{c}{16n}. \]

For each \( S \in \mathcal{B} \), let \( \alpha(S) = \min\{ s \in S \mid g \cdot s \neq s \} \). Then, since \( \ell > 2 \), it follows that the sets

\[ \mathcal{B} \cup \{ (S \setminus \{ \alpha(S) \}) \cup \{ t \} \mid S \in \mathcal{B}, t \in \Delta \setminus (S \cup \text{Fix}_\Delta(g)) \} \]
are distinct. Note that if $S \in \mathcal{B}$, then $|S \cup \text{Fix}_\Delta(g)| \leq 3n/4$; and it follows that $(1 + \frac{4}{n})|\mathcal{B}| \leq |\Omega|$ and so $|\mathcal{B}|/|\Omega| < 4/n$. If $c \geq 16$, then
\[
\frac{|\text{Fix}_\Omega(g)|}{|\Omega|} < \frac{c}{16n} + \frac{4}{n} < \frac{c}{16n} + \frac{c}{4n} < \frac{|\text{Fix}_\Delta(g)|}{2|\Delta|},
\]
while if $c < 16$, then
\[
\frac{|\text{Fix}_\Omega(g)|}{|\Omega|} < \frac{c}{16n} + \frac{4}{n} < \frac{5}{n}.
\]

\[\square\]

If $\mathcal{P}$ is a partition of $\Delta$, then the subsets $B \in \mathcal{P}$ will be called the blocks of $\mathcal{P}$; and if $s \in \Delta$, then $[s]_\mathcal{P}$ will denote the block of $\mathcal{P}$ which contains $s$.

**Lemma 6.3.** Let $\Omega$ be the set of partitions $\mathcal{P}$ of $\Delta$ into $\ell$-sets for some fixed divisor $\ell$ of $n$ such that $2 \leq \ell \leq n/2$. If $g \in \text{Alt}(\Delta)$ has prime order $p > 2$, then the normalized permutation character of the action $\text{Alt}(n) \cap \Omega$ satisfies $|\text{Fix}_\Omega(g)|/|\Omega| < 2/n$.

**Proof.** Let $\mathcal{P} \in \text{Fix}_\Omega(g)$. Then we define the integer $\alpha(\mathcal{P})$ as follows.

(a) If $\mathcal{P}$ contains a $g$-invariant block $B$ such that $g \mid B \neq \text{id}_B$, then $\alpha(\mathcal{P})$ is the least $s \in \Delta$ such that $[s]_\mathcal{P}$ is $g$-invariant and $g \cdot s \neq s$.

(b) Otherwise, $\alpha(\mathcal{P})$ is the least $s \in \Delta$ such that $g \cdot s \neq s$.

For each $t \in \Delta \setminus \{\alpha(\mathcal{P})\}_\mathcal{P}$, we define $\mathcal{P}(t) \in \Omega$ to be the partition obtained from $\mathcal{P}$ by replacing the block $[\alpha(\mathcal{P})]_\mathcal{P}$ by $([\alpha(\mathcal{P})]_\mathcal{P} \setminus \{\alpha(\mathcal{P})\}) \cup \{t\}$ and the block $[t]_\mathcal{P}$ by $([t]_\mathcal{P} \setminus \{t\}) \cup \{\alpha(\mathcal{P})\}$.

**Claim 6.4.** $\mathcal{P}(t) \notin \text{Fix}_\Omega(g)$.

**Proof of Claim 6.4.** First suppose that $\mathcal{P}$ contains a $g$-invariant block $B$ such that $g \mid B \neq \text{id}_B$. Then clearly $g \cdot [t]_{\mathcal{P}(t)} \neq [t]_{\mathcal{P}(t)}$; also, since $\ell \geq p > 2$, it follows that $g \cdot [t]_{\mathcal{P}(t)} \cap [t]_{\mathcal{P}(t)} \neq \emptyset$. Hence $\mathcal{P}(t) \notin \text{Fix}_\Omega(g)$.

Thus we can suppose that $\mathcal{P}$ does not contain a $g$-invariant block $B$ such that $g \mid B \neq \text{id}_B$. For each $0 \leq i < p$, let $S_i = g^i \cdot [\alpha(\mathcal{P})]_\mathcal{P}$. Since $p > 2$, there exists $0 < i < p$ such that $S_i \in \mathcal{P}(t)$. Since $S_0 = g^{p-i} \cdot S_i \notin \mathcal{P}(t)$, it follows that $\mathcal{P}(t) \notin \text{Fix}_\Omega(g)$.

If $\mathcal{P}, \mathcal{P}' \in \text{Fix}_\Omega(g)$ and $\mathcal{P}(t) = \mathcal{P}'(t')$, then it is easily checked that $\mathcal{P} = \mathcal{P}'$ and $t = t'$. Thus $(1 + n - \ell)|\text{Fix}_\Omega(g)| \leq |\Omega|$ and so $|\text{Fix}_\Omega(g)|/|\Omega| < 2/n$.

The following two results are routine generalizations of Lemmas 5.2 and 5.3 of Thomas-Tucker-Drob [16].

**Lemma 6.5.** For any $\varepsilon > 0$ and $0 < a \leq 1$ and $r \geq 0$, there exists an integer $d_{a,r,\varepsilon}$ such that if $d_{a,r,\varepsilon} \leq d \leq (n - r)/2$ and $H < \text{Alt}(\Delta)$ is any subgroup such that

(i) there exists an $H$-invariant subset $\Sigma \subseteq \Delta$ of cardinality $r$, and
(ii) $H$ acts imprimitively on $\Delta \setminus \Sigma$ with a proper system of imprimitivity $\mathcal{B}$ of blocks size $d$,

then for any element $g \in \text{Alt}(\Delta)$ satisfying $|\text{supp}(g)| \geq an$,
\[
\frac{|\{ s \in \text{Alt}(\Delta) \mid sgs^{-1} \in H \}|}{|\text{Alt}(\Delta)|} < \varepsilon.
\]
Lemma 6.6. For any $\varepsilon > 0$ and $0 < a \leq 1$, there exists an integer $r_{a,\varepsilon}$ such that if $r_{a,\varepsilon} \leq r \leq n/2$ and $H < \text{Alt}(\Delta)$ is a subgroup with an $H$-invariant set $\Sigma \subseteq \Delta$ of cardinality $|\Sigma| = r$, then for any element $g \in \text{Alt}(\Delta)$ satisfying $|\text{supp}(g)| \geq an$,
\[
\frac{|\{s \in \text{Alt}(\Delta) \mid sgs^{-1} \in H\}|}{|\text{Alt}(\Delta)|} < \varepsilon.
\]

For the sake of completeness, we will sketch the main points of the proofs of Lemmas 6.5 and 6.6. As in Thomas-Tucker-Drob [16, Section 5], our approach will be probabilistic; i.e. we will regard the normalized permutation character $E(6.3)$ and that $E(6.2)$ and that $E(6.1)$.

\[
\begin{align*}
E & (6.3) \\
E & (6.2) \\
E & (6.1)
\end{align*}
\]

For any $m > 0$ and an integer $m_0 \in \mathbb{N}$ such that $|a_m| \leq C|x_m|$ for all $m \geq m_0$. Also if $(c_m)$ is another sequence of real numbers, then we write $a_m = c_m + O(x_m)$ to mean that $a_m - c_m = O(x_m)$.

Sketch proof of Lemma 6.5. Suppose that $m = r + d\ell$, where $\ell \geq 2$, and that $H < \text{Alt}(\Delta)$ has an $H$-invariant set $\Sigma \subseteq \Delta$ of cardinality $|\Sigma| = r$ such that $H$ acts imprimitively on $T = \Delta \setminus \Sigma$ with a proper system of imprimitivity $B$ of blocksize $d$. Let $b = a/3$ and suppose that $g \in \text{Alt}(\Delta)$ satisfies $|\text{supp}(g)| \geq an = 3bn$. Then there exists a subset $Z \subseteq \text{supp}(g)$ such that $g(Z) \cap Z = \emptyset$ and $|Z| = cn$ for some $b \leq c \leq 1/2$. Fix an element $z_0 \in Z$ and let $y_0 = g(z_0)$. Let $s \in S$ be a uniformly random permutation. If $s(z_0), s(y_0) \in T$, let $B_0, C_0 \in B$ be the blocks in $B$ containing $s(z_0)$ and $s(y_0)$ respectively; otherwise, let $B_0 = C_0 = \emptyset$. Let
\[J(s) = \{z \in Z \setminus \{z_0\} \mid s(z) \in B_0 \text{ and } s(g(z)) \notin C_0\}.
\]

Note that if $J(s) \neq \emptyset$, then $sgs^{-1}(B_0)$ intersects at least two of the blocks of $B$ and thus $sgs^{-1} \notin H$. Hence it is enough to show that $p[|J(s)| > 0] > 1 - \varepsilon$ for all sufficiently large $d$ (depending only on $\varepsilon, a$ and $r$).

Since we wish to apply Lemma 6.7, we need to compute the asymptotics of the expectation and variance of the random variable $|J(s)|$. Arguing as in the proof of Thomas-Tucker-Drob [16, Lemma 5.2], it can be shown that
\[
\begin{align*}
(6.1) & \quad E[|J(s)|] = cd(1 - \frac{d}{m}) + O(1); \\
(6.2) & \quad E[|J(s)|^2] = [cd(1 - \frac{d}{m})]^2 + O(d); \\
(6.3) & \quad E[|J(s)|^2] = [cd(1 - \frac{d}{m})]^2 + O(d),
\end{align*}
\]
the implied constants needed to witness the big-O inequalities are only
dependent on the parameter $r$. Combining (6.2) and (6.3) we obtain that
$$\text{Var}(|J(s)|) = \mathbb{E}[|J(s)|^2] - \mathbb{E}[|J(s)|]^2 = O(d),$$
and hence $\text{Var}(|J(s)|)^{1/2} = O(\sqrt{d})$. Of course, (6.1) implies that $d = O(\mathbb{E}[|J(s)|])$.
Thus there exists a constant $C > 0$ such that $\sigma = \text{Var}(|J(s)|)^{1/2} \leq C\sqrt{d}$ and
$d \leq C\mathbb{E}[|J(s)|] = C\mu$ for all sufficiently large $d$. It follows that
$$\mu / \sigma \geq C^{-1} d / C \sqrt{d} = C^{-2} \sqrt{d} \rightarrow \infty \quad \text{as } d \rightarrow \infty.$$ Applying Lemma 6.7, we conclude that $\mathbb{P}[|J(s)| > 0] \rightarrow 1$ as $d \rightarrow \infty$. This completes the proof of Lemma 6.5. \hfill \Box

Sketch proof of Lemma 6.6. Let $b = a/3$. Suppose that $H < \text{Alt}(\Delta)$ has an $H$-
invariant set $\Sigma \subseteq \Delta$ of cardinality $|\Sigma| = r \leq n/2$ and that $g \in \text{Alt}(\Delta)$ satisfies
$|\text{supp}(g)| \geq an = 3bm$. Then, once again, there exists a subset $Z \subseteq \text{supp}(g)$ such that
$g(Z) \cap Z = \emptyset$ and $|Z| = cn$ for some $b \leq c \leq 1/2$. Let $s \in \text{Alt}(\Delta)$ be a
uniformly random permutation and let
$$I(s) = \{z \in Z \mid s(z) \in \Sigma \text{ and } s(g(z)) \notin \Sigma\}.$$ If $I(s) \neq \emptyset$, then $\Sigma$ is not $sgs^{-1}$-invariant and thus $sgs^{-1} \notin H$. Hence it is enough
to show that $\mathbb{P}[|I(s)| > 0] > 1 - \varepsilon$ for all sufficiently large $r$ (depending only on $\varepsilon$
and $a$).

Arguing as in the proof of Thomas-Tucker-Drob [16, Lemma 5.2], it can be shown that
\begin{equation}
\mathbb{E}[|I(s)|] = cr(1 - \frac{\varepsilon}{m}) + O(1);
\end{equation}
and that
\begin{equation}
\mathbb{E}[|I(s)|^2] = [cr(1 - \frac{\varepsilon}{m})]^2 + O(r);
\end{equation}
and that
\begin{equation}
\mathbb{E}[|I(s)|^2] = [cr(1 - \frac{\varepsilon}{m})]^2 + O(r),
\end{equation}
where the implied constants needed to witness the big-O inequalities are absolute. It follows that
$\text{Var}(|I(s)|)^{1/2} = O(\sqrt{r})$ and $r = O(\mathbb{E}[|I(s)|])$; and another application
of Lemma 6.7 shows that $\mathbb{P}[|I(s)| > 0] \rightarrow 1$ as $r \rightarrow \infty$. \hfill \Box

7. Full limits of finite alternating groups

In this section, we will first prove that a “full limit” of finite alternating groups
$G = \bigcup_{i \in \mathbb{N}} G_i$ has a nontrivial ergodic IRS if and only if $G = \bigcup_{i \in \mathbb{N}} G_i$ has linear
natural orbit growth. Then we will classify the ergodic IRSs of the $L(\text{Alt})$-groups
$G = \bigcup_{i \in \mathbb{N}} G_i$ with linear natural orbit growth.

Definition 7.1. Suppose that $G = \bigcup_{i \in \mathbb{N}} G_i$ is the union of the strictly increasing
chain of finite alternating groups $G_i = \text{Alt}(\Delta_i)$.
(i) The embedding $\text{Alt}(\Delta_i) \hookrightarrow \text{Alt}(\Delta_{i+1})$ is said to be full if $\text{Alt}(\Delta_i)$ has no trivial
orbits on $\Delta_{i+1}$.
(ii) $G = \bigcup_{i \in \mathbb{N}} G_i$ is the full limit of the finite alternating groups $G_i = \text{Alt}(\Delta_i)$ if
each embedding $\text{Alt}(\Delta_i) \hookrightarrow \text{Alt}(\Delta_{i+1})$ is full.
Warning 7.2. A composition of two full embeddings is not necessarily full. For example, suppose that $G_i \hookrightarrow G_{i+1}$ is any full embedding and that $\Delta_{i+2} = G_{i+1}/G_i$. Then the embedding $G_{i+1} \hookrightarrow G_{i+2}$ is also full, but the embedding $G_i \hookrightarrow G_{i+2}$ is not full. Consequently, if $G = \bigcup_{i \in \mathbb{N}} G_i$ is a full limit and $(k_i \mid i \in \mathbb{N})$ is a strictly increasing sequence of natural numbers, then $G = \bigcup_{i \in \mathbb{N}} G_{k_i}$ is not necessarily a full limit. The notion of a full limit is a purely technical one, introduced in order to formulate the following special case of Theorem 3.7, which will be proved in this section. (Of course, by Proposition 3.18, we already know that if a full limit $G = \bigcup_{i \in \mathbb{N}} G_i$ has linear natural orbit growth, then $G$ has a nontrivial ergodic IRS.)

Proposition 7.3. If $G = \bigcup_{i \in \mathbb{N}} G_i$ is a full limit of finite alternating groups, then $G$ has a nontrivial ergodic IRS if and only if $G = \bigcup_{i \in \mathbb{N}} G_i$ has linear natural orbit growth.

Until further notice, suppose that $G = \bigcup_{i \in \mathbb{N}} G_i$ is the full limit of the finite alternating groups $G_i = \text{Alt}(\Delta_i)$.

Lemma 7.4. Let $p > 2$ be an odd prime, let $a = 1/(p + 1)$ and let $n_{p,a}$ be the integer given by Lemma 6.1. Suppose that $|\Delta_{i_0}| \geq \max\{ n_{p,a}, 5(p+1) \}$ and that $g \in \text{Alt}(\Delta_{i_0})$ is an element of order $p$ such that $|\text{Fix}_{\Delta_{i_0}}(g)| \leq |\Delta_{i_0}|/(p+1)$. Then $|\text{Fix}_{\Delta_i}(g)| \leq |\Delta_i|/(p+1)$ for all $i \geq i_0$.

Proof. Let $i \geq i_0$ and suppose that $|\text{Fix}_{\Delta_i}(g)| \leq |\Delta_i|/(p+1)$. It is enough to show that if $\Omega$ is an orbit of $\text{Alt}(\Delta_i)$ on $\Delta_{i+1}$, then $|\text{Fix}_\Omega(g)|/|\Omega| \leq 1/(p+1)$. Let $\Omega \in \Omega$ and let $H = \{ h \in \text{Alt}(\Delta_i) \mid h \cdot \omega = \omega \}$ be the corresponding stabilizer. Let $K$ be a maximal proper subgroup of $\text{Alt}(\Delta_i)$ such that $H \leq K$ and let $\theta_K$ be the normalized permutation character of the action $\text{Alt}(\Delta_i) \rtimes \text{Alt}(\Delta_i)/K$. Then, applying Corollary 2.3, we have that $|\text{Fix}_\Omega(g)|/|\Omega| \leq \theta_K(g)$.

First suppose that $K$ acts primitively on $\Delta_i$. Let $g$ be a product of $a_i$ $p$-cycles when regarded as an element of $\text{Alt}(\Delta_i)$. Since $|\text{Fix}_{\Delta_i}(g)| \leq |\Delta_i|/(p+1)$, it follows that $a_i \geq |\Delta_i|/(p+1)$. Hence, by Lemma 6.1, we have that

$$\theta_K(g) < 1/|\Delta_i| < 1/(p+1).$$

Next suppose that $K$ acts imprimitively on $\Delta_i$, preserving a system of imprimitivity $\mathcal{P}$ of blocksize $2 \leq \ell \leq n/2$. Then $\text{Alt}(\Delta_i) \rtimes \text{Alt}(\Delta_i)/K$ is isomorphic to the action of $\text{Alt}(\Delta_i)$ on the set $\mathcal{P}$ of partitions of $\Delta_i$ into $\ell$-sets. Applying Lemma 6.3, we obtain that

$$\theta_K(g) < 2/|\Delta_i| < 1/(p+1).$$

Finally suppose that $K$ acts intransitively on $\Delta_i$, fixing set-wise a subset $S \subseteq \Delta_i$ of size $1 \leq \ell \leq n/2$. Then $\text{Alt}(\Delta_i) \rtimes \text{Alt}(\Delta_i)/K$ is isomorphic to the action of $\text{Alt}(\Delta_i)$ on $[\Delta_i]^\ell$. If $\ell = 1$, then $\theta_K(g) = |\text{Fix}_{\Delta_i}(g)|/|\Delta_i| \leq 1/(p+1)$. Hence we can suppose that $\ell \geq 2$. Applying Lemma 6.2, either

$$\theta_K(g) < 5/|\Delta_i| \leq 1/(p+1),$$

or else

$$\theta_K(g) < \frac{1}{2} |\text{Fix}_{\Delta_i}(g)|/|\Delta_i| \leq 1/2(p+1).$$

□

Corollary 7.5. $\limsup |\text{Fix}_{\Delta_i}(g)|/|\Delta_i| < 1$ for all $1 \neq g \in G$. 

Proof. Applying Lemma 7.4, it follows that there exists an element \( g \in G \) of order 3 such that \( \limsup |\text{Fix}_{\Delta_i}(g)|/|\Delta_i| \leq 1/4 \). On the other hand, it is easily checked that if \( \{ k_i \mid i \in \mathbb{N} \} \) is a strictly increasing sequence of natural numbers, then \( N = \{ g \in G \mid \lim_{n \to \infty} |\text{Fix}_{\Delta_k}(g)|/|\Delta_k| = 1 \} \) is a normal subgroup of \( G \). Since \( G \) is simple, the result follows. \( \square \)

For the rest of this section, suppose that \( \nu \neq \delta_1, \delta_G \) is an ergodic IRS of \( G \). Applying Creutz-Peterson [2, Proposition 3.3.1], we can suppose that \( \nu \) is the stabilizer distribution of an ergodic action \( G \acts \ (Z, \mu) \). Let \( \chi(g) = \mu(\text{Fix}_Z(g)) \) be the corresponding character. For each \( z \in Z \) and \( i \in \mathbb{N} \), let \( \Omega_i(z) = \{ g \cdot z \mid g \in G_i \} \).

Then, by Theorem 2.1, for \( \nu \)-a.e. \( z \in Z \), for all \( g \in G \), we have that
\[
\mu(\text{Fix}_Z(g)) = \lim_{i \to \infty} |\text{Fix}_{\Omega_i(z)}(g)|/|\Omega_i(z)|.
\]

Fix such an element \( z \in Z \) and let \( H = \{ h \in G \mid h \cdot z = z \} \) be the corresponding point stabilizer. Clearly we can suppose that the element \( z \in Z \) has been chosen such that \( H \notin \{ 1, G \} \) and also such that \( \chi(g) > 0 \) for all \( g \in H \). For each \( i \in \mathbb{N} \), let \( H_i = H \cap G_i \) and let \( n_i = |\Delta_i| \). Clearly \( G_i \acts \Omega_i(z) \) is isomorphic to \( G_i \acts G_i/H_i \).

**Lemma 7.6.** There exist only finitely many \( i \in \mathbb{N} \) such that the action \( H_i \acts \Delta_i \) is primitive.

Proof. Suppose that \( I = \{ i \in \mathbb{N} \mid H_i \acts \Delta_i \) is primitive \) is infinite. Since \( H \neq 1 \), there exists an element \( g \in H \) of some prime order \( p \). Let \( g \in G_i \) and for each \( i \geq i_0 \), let \( g \) be a product of \( a_i \) \( p \)-cycles when regarded as an element of \( G_i \). Then, by Corollary 7.5, there exists a constant \( a > 0 \) such that \( a_i \geq a n_i \) for all \( i \geq i_0 \).

Let \( n_{p,a} \) be the integer given by Lemma 6.1. Then \( |\text{Fix}_{\Omega_i(z)}(g)|/|\Omega_i(z)| < 1/n_i \) for all \( i \in I \) such that \( n_i \geq n_{p,a} \) and it follows that
\[
\chi(g) = \lim_{i \to \infty} |\text{Fix}_{\Omega_i(z)}(g)|/|\Omega_i(z)| = 0,
\]
which is a contradiction. \( \square \)

**Lemma 7.7.** For each integer \( d > 1 \), there exist only finitely many \( i \in \mathbb{N} \) such that \( H_i \acts \Delta_i \) preserving a maximal system \( B_i \) of imprimitivity of blocksize \( d \).

Proof. Suppose that there exists a fixed \( d > 1 \) and an infinite subset \( I \subseteq \mathbb{N} \) such that for all \( i \in I \), the subgroup \( H_i \acts \Delta_i \) preserving a maximal system \( B_i \) of imprimitivity of blocksize \( d \). Then \( H_i \) is isomorphic to a subgroup of the wreath product \( \text{Sym}(d) \wr \text{Sym}(n_i/d) \) for each \( i \in I \). Applying Stirling’s Approximation, it follows that there exist constants \( c, k \) such that for all \( n_i \),
\[
|\text{Sym}(d) \wr \text{Sym}(n_i/d)| < c k^n n^{n/d}.
\]

**Claim 7.8.** For all but finitely many \( i \in I \), the induced action of \( H_i \) on \( B_i \) contains \( \text{Alt}(B_i) \).

Proof of Claim 7.8. Suppose not and let \( g \in H \) be an element of some prime order \( p \). Let \( g \in G_i \) and for each \( i \geq i_0 \), let \( g \) be a product of \( a_i \) \( p \)-cycles when regarded as an element of \( G_i \). Applying Corollary 7.5, there exists a constant \( a > 0 \) such that \( a_i \geq a n_i \) for all \( i \geq i_0 \). Arguing as in the proof of Lemma 6.1, it follows that there are constants \( r, s \) such that
\[
|g^{G_i}| > r s^{n_i(n_i^{n_i})^{(p-1)a}}.
\]
Let $i \in I$ and let $\Gamma_i \leq \text{Sym}(B_i)$ be the group induced by the action of $H_i$ on $B_i$. Since $B_i$ is a maximal system of imprimitivity, it follows that $\Gamma_i$ is a primitive subgroup of $\text{Sym}(B_i)$. Hence, by Praeger-Saxl [12], if $\Gamma_i$ does not contain $\text{Alt}(B_i)$, then $|\Gamma_i| < 4^{n_i/d}$. Since $H_i$ is isomorphic to a subgroup of $\text{Sym}(d)$ wr $\Gamma_i$, it follows that

$$|H_i| < (d!)^{n_i/d} 4^{n_i/d} = t_n,$$

where $t = (d!)^{1/d}$, and so

$$\frac{|g^{\Gamma_i} \cap H_i|}{|g^{\Gamma_i}|} < \frac{|H_i|}{|g^{\Gamma_i}|} < \frac{t^{n_i}}{rs^{n_i}(n_i^{n_i})(p-1)^a}$$

It follows that

$$\chi(g) = \lim_{i \to \infty} |\text{Fix}_{\Xi_i}(z)(g)|/|\Xi_i(z)| = \lim_{i \to \infty} |g^{\Gamma_i} \cap H_i|/|g^{\Gamma_i}| = 0,$$

which is a contradiction. □

Let $a = 1/6$ and let $n_{5,a}$ be the integer given by Lemma 6.1. Let $i_0 \in I$ be such that $|\Delta_{n_i}| \geq \max\{n_{5,a}, 24d\}$ and such that the induced action of $H_{i_0}$ on $B_{i_0}$ contains $\text{Alt}(B_{i_0})$. Then there exists an element $g \in H_{i_0}$ of order 5 such that $g$ fixes setwise at most 4 blocks of $B_{i_0}$ and so $|\text{Fix}_{\Delta_{n_i}}(g)| \leq 4d \leq |\Delta_{n_i}|/6$. Applying Lemma 7.4, it follows that $|\text{Fix}_{\Delta_{n_i}}(g)| \leq |\Delta_i|/6$ for all $i \geq i_0$. For each $i \geq i_0$, let $g$ be a product of $a_i$-cycles when regarded as an element of $G_i$. Then it is easily checked that $a_i \geq n_i/6$. Hence, arguing as above, there exist constants $r, s$ such that

$$|g^{\Gamma_i}| > r s^{n_i}(n_i^{n_i})^{4/6}.$$ 

Hence, if $i_0 \leq i \in I$, we have that

$$\frac{|g^{\Gamma_i} \cap H_i|}{|g^{\Gamma_i}|} < \frac{|H_i|}{|g^{\Gamma_i}|} < \frac{ck^{n_i}s^{n_i/d}}{rs^{n_i}(n_i^{n_i})^{4/6}}.$$ 

Since $4/6 > 1/2 \geq 1/d$, it follows that $\chi(g) = 0$, which is a contradiction. □

**Lemma 7.9.** There exist only finitely many $i \in \mathbb{N}$ such that the action $H_i \acts \Delta_i$ is transitive.

**Proof.** Suppose not. Then, by Lemma 7.6, for all but finitely many $i \in \mathbb{N}$, the subgroup $H_i$ acts imprimitively on $\Delta_i$ with a maximal system of imprimitivity $B_i$ of blocksize $d_i$. Furthermore, by Lemma 7.7, we have that $d_i \to \infty$ as $i \to \infty$. Let $1 \neq h \in H_i$; say, $h \in H_i$. Then, by Corollary 7.5, there exist a constant $a > 0$ such that $|\text{supp}_{\Delta_j}(g)| \geq a|\Delta_j|$ for all $j \geq i$. But then Lemma 6.5 (in the case when $r = 0$) implies that

$$\chi(g) = \lim_{j \to \infty} \frac{|\{s \in G_j \mid sgs^{-1} \in H_i\}|}{|G_j|} = 0,$$

which is a contradiction. □

**Lemma 7.10.** There exists a constant $s$ such that for all but finitely many $i \in \mathbb{N}$, there exists a unique $H_i$-invariant subset $\Sigma_i \subseteq \Delta_i$ of cardinality $1 \leq r_i \leq s$ such that $H_i$ induces at least $\text{Alt}(\Omega_i)$ on $\Omega_i = \Delta_i \setminus \Sigma_i$.  

Hence, combining Lemma 7.10 and Corollary 2.3, we obtain that
\[ p > s \]
order
Then, applying Lemma 6.6, we see that there exists \( s \) such that \( 1 \leq r_i \leq s \) for all \( i \geq i_0 \). Furthermore, choosing \( i_0 \) so that \( |\Delta_{i_0}| \geq 4s \), it follows that for all \( i \geq i_0 \), there exists a unique \( H_i \)-invariant subset \( \Sigma_i \subseteq \Delta_i \) of cardinality \( r_i \) and that \( H_i \) acts transitively on \( \Omega_i = \Delta_i \setminus \Sigma_i \). Let \( \bar{H}_i \) be the subgroup of \( \text{Sym}(\Omega_i) \) induced by the action of \( H_i \) on \( \Omega_i \). Then, arguing as above, we first see that \( \bar{H}_i \) must act primitively on \( \Omega_i \) for all but finitely many \( i \geq i_0 \), and then that \( \text{Alt}(\Omega_i) \leq \bar{H}_i \) for all but finitely many \( i \geq i_0 \).

In particular, it follows that for every prime \( p \), there exists arbitrarily large \( i \in \mathbb{N} \) such that there exists an element \( g \in H_i \) of order \( p \) with \( |\text{Fix}_{\Delta_i}(g)| \leq |\Delta_i|/(p+1) \).

**Lemma 7.11.** If \( g \in H \) has prime order \( p > s \), then \( \lim \inf |\text{Fix}_{\Delta_i}(g)|/|\Delta_i| \neq 0 \).

**Proof.** Suppose that \( \lim \inf |\text{Fix}_{\Delta_i}(g)|/|\Delta_i| = 0 \) for some element \( g \in H \) of prime order \( p > s \). Let \( \theta_i, \psi_i \) be the normalized permutation characters of the actions \( G_i \acts \Delta_i/H_i \) and \( G_i \acts \Delta_i^{r_i} \). Since \( p > s \geq r_i \), it follows that
\[
|\text{Fix}_{\Delta_i^{r_i}}(g)| = |\text{Fix}_{\Delta_i}(g)|^{r_i}.
\]
Hence, combining Lemma 7.10 and Corollary 2.3, we obtain that
\[
\theta_i(g) \leq \psi_i(g) = \frac{|\text{Fix}_{\Delta_i}(g)|^{r_i}}{|\Delta_i|^{r_i}}
\]
and it follows that \( \chi(g) = \lim_{i \to \infty} \theta_i(g) = 0 \), which is a contradiction. \( \square \)

The following lemma completes the proof of Proposition 7.3.

**Lemma 7.12.** \( G \) has linear natural orbit growth.

**Proof.** Let \( p \) be a prime with \( p > s \), let \( a = 1/(p+1) \) and let \( n_{p,a} \) be the integer given by Lemma 6.1. Then there exists \( i_0 \) such that \( |\Delta_{i_0}| \geq \max \{ n_{p,a}, 5(p+1) \} \) and such that \( H_{i_0} \) contains an element \( g \) of order \( p \) such that \( |\text{Fix}_{\Delta_{i_0}}(g)| \leq |\Delta_{i_0}|/(p+1) \).

Applying Corollary 7.5, it follows that \( |\text{Fix}_{\Delta_i}(g)| \leq |\Delta_i|/(p+1) \) for all \( i \geq i_0 \). Furthermore, by Lemma 7.11, we can assume that \( |\text{Fix}_{\Delta_i}(g)| \geq 10 \) for all \( i \geq i_0 \). Suppose that \( \Phi \) is a non-natural orbit of \( G_i = \text{Alt}(\Delta_i) \) on \( \Delta_{i+1} \). Then, applying Corollary 2.3 and Lemmas 6.1, 6.2 and 6.3, it follows that
\[
|\text{Fix}_\Phi(g)|/|\Phi| < \max \left\{ \frac{5}{|\Delta_i|}, \frac{|\text{Fix}_{\Delta_i}(g)|/2|\Delta_i|}{|\Delta_i|/2} \right\} = \frac{|\text{Fix}_{\Delta_i}(g)|}{2|\Delta_i|};
\]
and it follows that
\[
|\text{Fix}_{\Delta_i^{r_i}}(g)| \leq s_{i+1} n_i \frac{|\text{Fix}_{\Delta_i}(g)|}{|\Delta_i|} + (n_{i+1} - s_{i+1} n_i) \frac{|\text{Fix}_{\Delta_i}(g)|}{2|\Delta_i|}
\]
\[= \frac{(2n_{i+1} - s_{i+1}) |\text{Fix}_{\Delta_i}(g)|}{2|\Delta_i|}.\]
It follows that for all \( i \geq i_0 \),
\[
|\text{Fix}_{\Delta_i^{r_i}}(g)|/|\Delta_{i+1}| \leq \left( 1 - \frac{e_{i+1}}{2n_{i+1}} \right) |\text{Fix}_{\Delta_i}(g)|/|\Delta_i|.\]
Since $\lim \inf |\text{Fix}_{\Delta_i}(g)|/|\Delta_i| \neq 0$, it follows that the infinite product

$$\prod_{i=i_0}^{\infty} \left(1 - \frac{e_{i+1}}{2n_{i+1}}\right)$$

(7.1)

converges to a nonzero real. Hence the same is true of the infinite product

$$\prod_{i=i_0}^{\infty} \left(1 - \frac{e_{i+1}}{2n_{i+1}}\right) = \prod_{i=i_0}^{\infty} \left(1 + \frac{e_{i+1}}{2n_{i+1} - e_{i+1}}\right),$$

and this implies that

$$\sum_{i=i_0}^{\infty} \frac{e_{i+1}}{2n_{i+1} - e_{i+1}} < \infty.$$ 

Of course, since the infinite product (7.1) converges to a nonzero real, it follows that $\lim_{i \to \infty} e_{i+1}/n_{i+1} = 0$; and hence there exists $i_1 \geq i_0$ such that for all $i \geq i_1$,

$$2n_{i+1} - e_{i+1} \leq 3(n_{i+1} - e_{i+1}).$$

It follows that

$$\sum_{i=i_1}^{\infty} \frac{e_{i+1}}{n_{i+1} - e_{i+1}} = 3 \sum_{i=i_1}^{\infty} \frac{e_{i+1}}{3(n_{i+1} - e_{i+1})} \leq 3 \sum_{i=i_1}^{\infty} \frac{e_{i+1}}{2n_{i+1} - e_{i+1}} < \infty;$$

and, arguing as above, this implies that the infinite product

$$\prod_{i=i_1}^{\infty} \left(1 - \frac{e_{i+1}}{n_{i+1}}\right)$$

converges to a nonzero real. Next notice that if $i < j$, then

$$\frac{s_{ij}}{n_j} = \frac{1}{n_i} \cdot \frac{s_{i+1}n_i}{n_{i+1}} \cdot \frac{s_{i+2}n_{i+1}}{n_{i+2}} \cdot \cdots \cdot $$

and hence

$$a_{i_1} = \lim_{j \to \infty} \frac{s_{i_1j}}{n_j} = \frac{1}{n_{i_1}} \prod_{i=i_1}^{\infty} \frac{s_{i+1}n_i}{n_{i+1}}.$$ 

Finally, since $s_{i+1}n_i = n_{i+1} - e_{i+1}$, it follows that

$$a_{i_1} = \frac{1}{n_{i_1}} \prod_{i=i_1}^{\infty} \frac{s_{i+1}n_i}{n_{i+1}} = \frac{1}{n_{i_1}} \prod_{i=i_1}^{\infty} \left(1 - \frac{e_{i+1}}{n_{i+1}}\right) > 0.$$ 

□

In the remainder of this section, via a slight modification of the above argument, we will prove that if $G = \bigcup_{i \in \mathbb{N}} G_i$ has linear natural orbit growth, then the ergodic IRSs of $G$ are $\{\delta_i, \delta_G\} \cup \{\nu_r | r \in \mathbb{N}^+\}$, where $\nu_r$ is the stabilizer distribution of the ergodic action $G \cap (\Delta^r, m^\otimes r)$.

For the remainder of this section, suppose that $G = \bigcup_{i \in \mathbb{N}} G_i$ has linear natural orbit growth. Note that we are not assuming that $G = \bigcup_{i \in \mathbb{N}} G_i$ is a full limit. Let $\nu \neq \delta_i, \delta_G$ be an ergodic IRS of $G$. As usual, for each $H \in \text{Sub}_{G_i}$, we will write $H_i = H \cap G_i$.

**Lemma 7.13.** There exists a constant $s$ such that if $H \subset G_i$ is a $\nu$-generic subgroup, then for all but finitely many $i \in \mathbb{N}$, there exists a unique $H_i$-invariant subset $\Sigma_i \subseteq \Delta_i$ of cardinality $1 \leq r_i \leq s$ such that $H_i$ induces at least $\text{Alt}(\Omega_i)$ on $\Omega_i = \Delta_i \setminus \Sigma_i$.
Before sketching the proof of Lemma 7.13, we will first complete the proof of Theorem 3.19. Suppose that $H \in \text{Sub}_G$ is a $\nu$-generic subgroup. Let $i_0$ be an integer such that for all $i \geq i_0$, there exists a unique $H_i$-invariant subset $\Sigma_i \subseteq \Delta_i$ of cardinality $1 \leq r_i \leq s$ such that $H_i$ induces at least $\text{Alt}(\Omega_i)$ on $\Omega_i = \Delta_i \setminus \Sigma_i$ and such that $|\text{Alt}(\Omega_{i_0})| \gg s!$. For each $i \geq i_0$, let $\pi_i : H_i \rightarrow \text{Sym}(\Sigma_i)$ be the homomorphism defined by $g \mapsto g | \Sigma_i$ and let $K_i = \ker \pi_i$. Since $[H_i : K_i] \leq s!$, it follows that $K_i = \text{Alt}(\Omega_i)$. Also note that since $[H_{i+1} : K_{i+1}] \leq s!$, it follows that $[K_i : K_i \cap K_{i+1}] \leq s!$ and hence $K_i \leq K_{i+1}$. Let $K = \bigcup_{i \geq i_0} K_i$. Since $K_i$ is the unique largest factor of the socle of $H_i$, it follows that the map $H \rightarrow K$ is $G$-equivariant and hence there is an associated ergodic IRS $\tilde{\nu}$ which concentrates on the corresponding subgroups $K \leq H$. Applying Theorem 3.23, it follows that there exists $1 \leq r \leq s$ such that $\tilde{\nu}$ is the stabilizer distribution $\nu_r$ of $G \acts (\Delta^r, m^{\otimes r})$, where $G \acts (\Delta, m)$ is the canonical ergodic action. Hence, in order to complete the proof of Theorem 3.19, it is enough to show that $H = K$ for $\nu$-a.e. $H \in \text{Sub}_G$. To see this, let $H \in \text{Sub}_G$ be such that the corresponding subgroup $K$ is the stabilizer of the sequence $(x_1, \ldots, x_r) \in \Delta^r$. For each $j \in \mathbb{N}$, let $\Sigma_j = \{ x_\ell | \Delta_j | 1 \leq \ell \leq r \}$. Then

$$K_j = \text{Alt}(\Delta_j \setminus \Sigma_j) \leq H_j \leq \text{Sym}(\Delta_j \setminus \Sigma_j) \times \text{Sym}(\Sigma_j),$$

and hence $K \leq H$. By Proposition 3.20, the stabilizer $G_x$ is self-normalizing for $m^{\otimes r}$-a.e. $x \in \Delta^r$ and this means that $H = K$ for $\nu$-a.e. $H \in \text{Sub}_G$. This completes the proof of Theorem 3.19.

The proof of Lemma 7.13 is almost identical to that of Lemma 7.10, so we will only sketch the main points. First the following argument shows that Corollary 7.5 also holds when $G = \bigcup_{i \in \mathbb{N}} G_i$ has linear orbit growth.

**Lemma 7.14.** For each $\varepsilon > 0$, there exists $i_\varepsilon \in \mathbb{N}$ such that if $i_\varepsilon \leq i < j$ and $g \in G_i$, then $|\text{supp}_{\Delta_j}(g)|/|\Delta_j| \geq (1 - \varepsilon) |\text{supp}_{\Delta_i}(g)|/|\Delta_i|.$

**Proof.** If $i < j$ and $g \in G_i$, then

$$|\text{supp}_{\Delta_j}(g)|/|\Delta_j| \geq \frac{s_{ij}}{n_j} |\text{supp}_{\Delta_i}(g)| \geq a_i |\text{supp}_{\Delta_i}(g)|.$$

Since Lemma 3.15 implies that $\lim_{i \rightarrow \infty} (1 - n_i a_i) = 0$, the result follows. \hfill $\square$

**Corollary 7.15.** $\limsup |\text{Fix}_{\Delta_j}(g)|/|\Delta_j| < 1$ for all $1 \neq g \in G$.

Using Corollary 7.15, we can now repeat the proofs of Lemmas 7.6, 7.7, 7.9 and 7.10, except for the final paragraph of the proof of Lemma 7.7, where we require that there exists an element $g \in H$ such that $\liminf |\text{supp}_{\Delta_j}(g)|/|\Delta_j| \geq 5/6$. To see that such an element exists, first note that the proof of Claim 7.8 goes through in this setting. Thus we can suppose that there exists an integer $i_0$ such that the following conditions hold:

(a) $H_{i_0}$ acts primitively on $\Delta_{i_0}$ preserving a maximal system $\mathcal{B}_{i_0}$ of primitivity of blocksize $d$.

(b) The induced action of $H_{i_0}$ on $\mathcal{B}_{i_0}$ contains $\text{Alt}(\mathcal{B}_{i_0})$.

(c) $(n_{i_0} - 4d)/n_{i_0} \geq 99/100$.

Furthermore, by Lemma 7.14, we can suppose that $i_0$ has been chosen so that if $i \geq i_0$ and $g \in G_i$, then

$$|\text{supp}_{\Delta_i}(g)|/|\Delta_i| \geq \frac{99}{100} |\text{supp}_{\Delta_{i_0}}(g)|/|\Delta_{i_0}|.$$
Let \( g \in H_{i_0} \) be an element of order 5 such that \( g \) fixes setwise at most 4 blocks of \( B_{i_0} \). Then
\[
\frac{|\text{supp}_{\Delta_i}(g)|}{|\Delta_i|} \geq \frac{n_{i_0} - 4d}{n_{i_0}} \geq \frac{99}{100}.
\]
and it follows that for all \( i \geq i_0 \),
\[
\frac{|\text{supp}_{\Delta_i}(g)|}{|\Delta_i|} \geq \frac{99}{100} \cdot \frac{|\text{supp}_{\Delta_{i_0}}(g)|}{|\Delta_{i_0}|} \geq \frac{99}{100} \cdot \frac{99}{100} \geq \frac{5}{6}.
\]
This completes our sketch of the proof of Lemma 7.13.

8. Arbitrary limits of finite alternating groups

In this section, we will first prove that if \( G \) is an \( L(\text{Alt}) \)-group with a nontrivial ergodic IRS, then \( G \) can be expressed as an almost diagonal limit of finite alternating groups. Then we will classify the ergodic IRSs of the almost diagonal groups \( G = \bigcup_{i \in \mathbb{N}} G_i \) with sublinear natural orbit growth such that \( G \not\cong \text{Alt}(\mathbb{N}) \). The ergodic IRSs of \( \text{Alt}(\mathbb{N}) \) will be described in Section 9. Throughout this section, let \( G = \bigcup_{i \in \mathbb{N}} G_i \) be the (not necessarily full) union of the increasing chain of finite alternating groups \( G_i = \text{Alt}(\Delta_i) \) and suppose that \( G \not\cong \text{Alt}(\mathbb{N}) \).

**Lemma 8.1.** For each \( i \in \mathbb{N} \), the number \( c_{ij} \) of nontrivial \( G_i \)-orbits on \( \Delta_j \) is unbounded as \( j \to \infty \).

**Proof.** By Hall [4, Theorem 5.1], if there exist \( i, c \in \mathbb{N} \) such that \( G_i \) has at most \( c \) nontrivial orbits on \( \Delta_j \) for all \( j > i \), then \( G \cong \text{Alt}(\mathbb{N}) \), which is a contradiction.

Hence, after passing to a suitable subsequence, we can suppose that each \( G_i \) has at least 2 nontrivial orbits on \( \Delta_i+1 \). Of course, since \( G_i \) is simple, this implies that if \( 1 \neq G_i' \leq G_i \), then \( G_i' \) also has at least 2 nontrivial orbits on \( \Delta_i+1 \). For each \( \ell \in \mathbb{N} \), we define sequences of subsets \( \Delta^j_{\ell} \subseteq \Delta_j \) and subgroups \( G(\ell)_j = \text{Alt}(\Delta^j_{\ell}) \) for \( j \geq \ell \) inductively as follows:

- \( \Delta^j_{\ell} = \Delta_{\ell} \);
- \( \Delta^j_{\ell+1} = \Delta_{j+1} \setminus \text{Fix}_{\Delta_{j+1}}(G(\ell)_j) \).

Clearly each \( G(\ell)_j \) is strictly contained in \( G(\ell)_{j+1} \) and \( G(\ell) = \bigcup_{\ell \leq j \in \mathbb{N}} G(\ell)_j \) is the full limit of the alternating groups \( G(\ell)_j = \text{Alt}(\Delta^j_{\ell}) \). It is also easily checked that if \( \ell < m \) and \( i < j \), then
\[
G_{\ell} \leq G(\ell)_j \leq G(m)_i < G(m)_j.
\]
It follows that if \( \ell < m \), then \( G(\ell) \leq G(m) \) and that \( G = \bigcup_{\ell \in \mathbb{N}} G(\ell) \). For the rest of this section, suppose that \( \nu \neq \delta_1, \delta_G \) is an ergodic IRS of \( G \).

**Lemma 8.2.** \( G(\ell) = \bigcup_{\ell \leq j \in \mathbb{N}} G(\ell)_j \) has linear natural orbit growth for all but finitely many \( \ell \in \mathbb{N} \).

**Proof.** Otherwise, by Proposition 7.3, there exists an infinite subset \( I \subseteq \mathbb{N} \) such that for each \( \ell \in I \), the only ergodic IRS of \( G(\ell) \) are \( \delta_1 \) and \( \delta_G(\ell) \). For each \( \ell \in I \), let \( f_\ell : \text{Sub}_{G(\ell)} \to \text{Sub}_{G(\ell)} \) be the Borel map defined by \( H \mapsto H \cap G(\ell) \). Then the map \( f_\ell \) is \( G(\ell) \)-equivariant and hence \( \nu_{G(\ell)} = (f_\ell)_* \nu \) is a (not necessarily ergodic) IRS of \( G(\ell) \). It follows that for \( \nu \)-a.e. \( H \in \text{Sub}_{G(\ell)} \), for all \( \ell \in I \), either \( H \cap G(\ell) = 1 \) or \( G(\ell) \leq H \). Since \( G = \bigcup_{\ell \in I} G(\ell) \), this implies that for \( \nu \)-a.e. \( H \in \text{Sub}_{G(\ell)} \), either \( H = 1 \) or \( H = G \), which is a contradiction. \( \square \)
Hence we can suppose that $G(\ell) = \bigcup_{\ell \in \mathbb{N}} G(\ell)_j$ has linear natural orbit growth for all $\ell \in \mathbb{N}$. Let $G(\ell) \cap (\Delta_\ell, m_\ell)$ be the canonical ergodic action and for each $r \in \mathbb{N}^+$, let $\nu(\ell)_r$ be the stabilizer distribution of $G(\ell) \cap (\Delta_\ell, m_\ell^{*r})$. Let $\nu_{G(\ell)}$ be the (not necessarily ergodic) IRS of $G(\ell)$ arising from the $G(\ell)$-equivariant map $\text{Sub}_G \to \text{Sub}_{G(\ell)}$ defined by $H \mapsto H \cap G(\ell)$. Then Theorem 3.19 implies that there exist $\alpha(\ell), \beta(\ell), \gamma(\ell)_r \in [0,1]$ with $\alpha(\ell) + \beta(\ell) + \sum_{r \in \mathbb{N}^+} \gamma(\ell)_r = 1$ such that

$$
(8.1) \quad \nu_{G(\ell)}(\ell) = \alpha(\ell)\delta_1 + \beta(\ell)\delta_{G(\ell)} + \sum_{r \in \mathbb{N}^+} \gamma(\ell)_r \nu(\ell)_r.
$$

Let $H \in \text{Sub}_G$ be a $\nu$-generic subgroup and let $\ell_0 \in \mathbb{N}$ be the least integer such that $1 < H \cap G(\ell_0) < G(\ell_0)$. Then equation (8.1) implies that for each $\ell \geq \ell_0$, there exist $i_\ell \geq 0$ and $r_\ell \geq 1$ such that for all $j \geq i_\ell$, there exists $\Sigma^f_j \in [\Delta^f_j]^{r_\ell}$ such that

$$
H \cap G(\ell) = H \cap \text{Alt}(\Delta^f_j) = \text{Alt}(\Delta^f_j \setminus \Sigma^f_j)
$$

and such that $\Sigma^f_j$ is contained in the union of the natural $G(\ell)$-orbits on $\Delta^f_j$ for all $k > j$. Define $i_\ell = \ell$ for $0 \leq \ell < \ell_0$ and let $f_H \in \mathbb{N}^0$ be the function defined by $f_H(\ell) = i_\ell$. Applying the Borel-Cantelli Lemma, it follows that there exists a fixed function $f \in \mathbb{N}^0$ such that for $\nu$-a.e. $H \in \text{Sub}_G$, for all but finitely many $\ell \in \mathbb{N}$, we have that $f_H(\ell) \leq f(\ell)$. Let $(j_\ell | \ell \in \mathbb{N})$ be a strictly increasing sequence of integers such that $j_\ell \geq \max\{ f(k) | k \leq \ell \}$. For each $\ell \in \mathbb{N}$, let $\Sigma_\ell^f = \Delta_\ell^f$ and let $G^f_\ell = \text{Alt}(\Delta^f_\ell)$. Then it is easily checked that if $k < \ell$, then $G^f_k < G^f_\ell$ and that $G = \bigcup_{\ell \in \mathbb{N}} G^f_\ell$.

Suppose that $H \in \text{Sub}_G$ is a $\nu$-generic subgroup. Then there exists an integer $\ell_H \in \mathbb{N}$ such that $i_\ell = f_H(\ell) \leq f(\ell)$ for all $\ell \geq \ell_H$. Let $\ell \geq \ell_H$. Then, since

$$
\langle \ell \rangle \geq \max\{ f(\ell), f(\ell + 1) \} \geq \max\{ i_\ell, i_{\ell + 1} \}
$$

and $\Delta^{f}_{j_{\ell + 1}} \subseteq \Delta^{f}_{j_{\ell}} \subseteq \Delta_{j_{\ell + 1}}$, it follows that there exist subsets $\Sigma^{f}_{j_{\ell + 1}} \subseteq [\Delta^{f}_{j_{\ell}}]^{r_{\ell + 1}}$ and $\Sigma^{f}_{j_{\ell + 1}} \subseteq [\Delta^{f}_{j_{\ell}}]^{r_{\ell + 1}}$ such that

$$
\text{Alt}(\Delta^{f}_{j_{\ell + 1}} \setminus \Sigma^{f}_{j_{\ell + 1}}) = H \cap \text{Alt}(\Delta^{f}_{j_{\ell + 1}}) \leq H \cap \text{Alt}(\Delta^{f}_{j_{\ell + 1}}) = \text{Alt}(\Delta^{f}_{j_{\ell + 1}} \setminus \Sigma^{f}_{j_{\ell + 1}}).
$$

This implies that $\Sigma^{f}_{j_{\ell + 1}} = \Sigma^{f}_{j_{\ell + 1}} \setminus \Delta^{f}_{j_{\ell + 1}}$. Since $j_\ell \geq f(\ell) \geq i_\ell$, it follows that $\Sigma^{f}_{j_{\ell + 1}}$ is contained in the union of the natural $G(\ell)$-orbits on $\Delta^{f}_{j_{\ell + 1}}$; and since $\Delta^{f}_{j_{\ell + 1}} \setminus \Delta^{f}_{j_{\ell + 1}} \subseteq \text{Fix}_{\Delta^{f}_{j_{\ell + 1}}}(G(\ell)_{j_\ell})$, it follows that $\Sigma^{f}_{j_{\ell + 1}}$ is contained in the union of the natural and trivial $G(\ell)$-orbits on $\Delta^{f}_{j_{\ell + 1}}$. In other words, writing $\Sigma^f = \Sigma^{f}_{j_{\ell + 1}}$, we have shown that for all $\ell \geq \ell_H$,

(i) $H_{\ell}^f = H \cap G^f_\ell = \text{Alt}(\Delta^f \setminus \Sigma^f)$; and

(ii) $\Sigma^f_{\ell + 1}$ is contained in the union of the natural and trivial $G^f_\ell$-orbits on $\Delta^f_{\ell + 1}$.

First suppose that $G = \bigcup_{\ell \in \mathbb{N}} G^f_\ell$ has linear natural orbit growth with the associated parameters $n^f_\ell$, $s^f_{k\ell}$, etc. Then we can suppose that $a^f_\ell = \lim_{k \to \infty} s^f_{k\ell}/n^f_\ell > 0$ for all $\ell \in \mathbb{N}$; and it follows by Remark 3.17 that $G = \bigcup_{\ell \in \mathbb{N}} G^f_\ell$ is an almost diagonal limit.

Hence we can suppose that $G = \bigcup_{\ell \in \mathbb{N}} G^f_\ell$ has sublinear natural orbit growth. Let $\Sigma^f$ be the associated space of sequences $(\Sigma^f_\ell)_{\ell \geq \ell_0}$, as defined in Section 4; and let $f : \Sigma^f \to \text{Sub}_G$ be the injective $G$-equivariant map defined by

$$
(\Sigma^f_\ell)_{\ell \geq \ell_0} \mapsto \bigcup_{\ell \geq \ell_0} \text{Alt}(\Delta^f_\ell \setminus \Sigma^f_\ell).
$$
Then $\nu$ concentrates on $f(\Sigma')$ and it follows that $\mu = f_*^{-1}\nu$ is a nonatomic $G$-invariant ergodic probability measure on $\Sigma'$. Applying Theorem 5.1, it follows that $G = \bigcup_{i \in \mathbb{N}} G_i$ is an almost diagonal limit. This completes the proof that if $G$ is an $L(\text{Alt})$-group with a nontrivial ergodic IRS, then $G$ can be expressed as an almost diagonal limit of finite alternating groups. For use in the next paragraph, also note that by Theorem 5.1, there exists $\gamma \in (0, \infty)$ such that $\nu = \nu_\beta^{\Sigma'}$.

Finally we will prove that if $G = \bigcup_{i \in \mathbb{N}} G_i$ is an almost diagonal limit with sublinear natural orbit growth and $G \not\cong \text{Alt}(\mathbb{N})$, then the ergodic IRSs of $G$ are
\[
\{ \delta_1, \delta_G \} \cup \{ \nu_\beta^\Sigma \mid \beta \in (0, \infty) \}.
\]

Note that the above analysis shows that if $\nu \neq \delta_1$, $\delta_G$ is an ergodic IRS of $G$, then there exists
\begin{itemize}
  \item a strictly increasing sequence of integers $(j_\ell \mid \ell \in \mathbb{N})$, and
  \item subsets $\Delta'_\ell \subseteq \Delta_{j_\ell}$
\end{itemize}
such that, letting $G'_\ell = \text{Alt}(\Delta'_\ell)$, we have that
\begin{itemize}
  \item $G = \bigcup_{i \in \mathbb{N}} G'_i$ is an almost diagonal limit, and
  \item there exists $\gamma \in (0, \infty)$ such that $\nu = \nu_\beta^{\Sigma'}$, where $\Sigma'$ is the associated space of sequences $(\Sigma'_i)_{i \geq \ell_0}$.
\end{itemize}

We must show that there exists $\beta \in (0, \infty)$ such that $\nu_\beta^\Sigma = \nu_\beta^{\Sigma'}$. Note that $G'_\ell \subseteq G_{j_\ell}$ for each $\ell \in \mathbb{N}$. By Theorem 5.7, after passing to a suitable subsequence of $(j_\ell \mid \ell \in \mathbb{N})$ if necessary, we can suppose that $G_{j_\ell} \subseteq G'_{\ell+1}$ for each $\ell \in \mathbb{N}$. By a second application of Theorem 5.7, we can suppose that $j_\ell = \ell$ for all $\ell \in \mathbb{N}$. (We only make this assumption in order to simplify notation.) Appealing twice more to Theorem 5.7, we now see that it is enough to show that the increasing chain
\[
G'_0 \subseteq G_0 \subseteq G'_1 \subseteq G_1 \subseteq \cdots \subseteq G'_\ell \subseteq G_\ell \subseteq \cdots
\]
is an almost diagonal limit. Let $\Delta''_{2i} = \Delta'_i$ and let $\Delta''_{2i+1} = \Delta_i$. Let $G''_i = \text{Alt}(\Delta''_i)$. Let $s'_i, e'_i$ be the parameters associated with the union $G = \bigcup_{i \in \mathbb{N}} G''_i$. Then clearly $s''_{2i} = 1$ and $e''_{2i+1} = 0$. Also, since $\text{supp}_D(G_i) \subseteq \text{supp}_D(G''_{i+1}) = \Delta''_{i+1}$, it follows that $s''_{2i+2} = s_{i+1}$ and $e''_{2i+2} = e_{i+1}$. Thus $\sum_{i=1}^{\infty} e'_i / s'_i = \sum_{i=1}^{\infty} e_i / s_0 < \infty$. This completes the proof of Theorem 4.15.

9. THE ERGODIC IRS OF $\text{Alt}(\mathbb{N})$

In this section, adapting and slightly correcting Vershik’s analysis of the ergodic IRSs of the group $\text{Fin}(\mathbb{N})$ of finitary permutations of the natural numbers, we will state the classification of the ergodic IRSs of the infinite alternating group $\text{Alt}(\mathbb{N})$ and we will characterize the ergodic actions $\text{Alt}(\mathbb{N}) \ltimes (\mathbb{Z}, \mu)$ such that the associated character $\chi(g) = \mu(\text{Fix}_Z(g))$ is indecomposable.

Recall that $\text{Fin}(\mathbb{N}) = \{ g \in \text{Sym}(\mathbb{N}) \mid \text{supp}(g) < \infty \}$. Throughout this section, if $g \in \text{Fin}(\mathbb{N})$, then $c_n(g)$ denotes the number of cycles of length $n > 1$ in the cyclic decomposition of the permutation $g$ and $\text{sgn} : \text{Fin}(\mathbb{N}) \to C = \{ \pm 1 \}$ is the homomorphism defined by
\[
\text{sgn}(g) = \begin{cases} 1, & \text{if } g \in \text{Alt}(\mathbb{N}); \\ -1, & \text{otherwise}. \end{cases}
\]

Vershik’s analysis of the ergodic IRSs of $\text{Fin}(\mathbb{N})$ is based upon the following two insights.
Theorem 9.1. If $\nu$ is an ergodic IRS of $\text{Alt}(\mathbb{N})$, then there exists $\alpha$, $A$ as above such that $\nu = \nu_{A}^{\alpha}$.

There exist examples of sequences $\alpha$ and distinct subgroups $A$, $A'$ such that $\nu_{A}^{\alpha} = \nu_{A'}^{\alpha}$. However, since for $\mu_{\alpha}$-a.e. $\xi \in \mathbb{N}^{N}$, 

$$\lim_{n \to \infty} |B_{i}^{\xi} \cap \{0,1,\ldots,n-1\}|/n = \alpha_{i},$$

it follows that if $\alpha \neq \alpha'$ and $A$, $A'$ are subgroups of $E_{\alpha}$, $E_{\alpha'}$, then $\nu_{A}^{\alpha} \neq \nu_{A'}^{\alpha'}$. The remainder of this section is devoted to the proof of the following result.

(i) If $H \leq \text{Fin}(\mathbb{N})$ is a random subgroup, then the corresponding $H$-orbit decomposition $\mathbb{N} = \bigsqcup_{i \in I} B_{i}$ is a random partition of $\mathbb{N}$, and these have been classified by Kingman [6].

(ii) The induced action of $H$ on an infinite orbit $B_{i}$ can be determined via an application of Wielandt’s theorem [20, Satz 9.4], which states that $\text{Alt}(\mathbb{N})$ and $\text{Fin}(\mathbb{N})$ are the only primitive subgroups of $\text{Fin}(\mathbb{N})$.

With minor modifications, the same ideas apply to the ergodic IRSs of $\text{Alt}(\mathbb{N})$, which can be classified as follows. Suppose that $\alpha = (\alpha_{i})_{i \in \mathbb{N}} \in [0,1]^{\mathbb{N}}$ is a sequence such that:

- $\alpha_{1} \geq \alpha_{2} \geq \cdots \geq \alpha_{i} \geq \cdots \geq 0$; and
- $\sum_{i=0}^{\infty} \alpha_{i} = 1$.

Then we can define a probability measure $p_{\alpha}$ on $\mathbb{N}$ by $p_{\alpha}(\{i\}) = \alpha_{i}$. Let $\mu_{\alpha}$ be the corresponding product probability measure on $\mathbb{N}^{N}$. Then $\text{Alt}(\mathbb{N})$ acts ergodically on $(\mathbb{N}^{N}, \mu_{\alpha})$ via the shift action $(\gamma \cdot \xi)(n) = \xi(\gamma^{-1}(n))$. For each $\xi \in \mathbb{N}^{N}$ and $i \in \mathbb{N}$, let $B_{i}^{\xi} = \{ n \in \mathbb{N} | \xi(n) = i \}$. Then for $\mu_{\alpha}$-a.e. $\xi \in \mathbb{N}^{N}$, the following statements are equivalent for all $i \in \mathbb{N}$.

(a) $\alpha_{i} > 0$.
(b) $B_{i}^{\xi} \neq \emptyset$.
(c) $B_{i}^{\xi}$ is infinite.
(d) $\lim_{n \to \infty} |B_{i}^{\xi} \cap \{0,1,\ldots,n-1\}|/n = \alpha_{i}$.

In this case, we say that $\xi$ is $\mu_{\alpha}$-generic.

First suppose that $\alpha_{0} \neq 1$, so that $I = \{ i \in \mathbb{N}^{+} | \alpha_{i} > 0 \} \neq \emptyset$. Let $S_{\alpha} = \bigsqcup_{i \in I} C_{i}$, where each $C_{i} = \{ \pm 1 \}$ is cyclic of order 2, and let $E_{\alpha} \leq S_{\alpha}$ be the subgroup consisting of the elements $(\varepsilon_{i})_{i \in I}$ such that $|\{ i \in I | \varepsilon_{i} = -1 \}|$ is even. Then for each subgroup $A \leq E_{\alpha}$, we can define a corresponding $\text{Alt}(\mathbb{N})$-equivariant Borel map

$$f_{A}^{\alpha} : \mathbb{N}^{N} \to \text{Sub}_{\text{Alt}(\mathbb{N})}$$

as follows. If $\xi$ is $\mu_{\alpha}$-generic, then $H_{\xi} = s_{\xi}^{-1}(A)$, where $s_{\xi}$ is the homomorphism

$$s_{\xi} : \bigsqcup_{i \in I} \text{Fin}(B_{i}^{\xi}) \to \bigsqcup_{i \in I} C_{i}$$

$(\pi_{i}) \mapsto (\text{sgn}(\pi_{i}))$.

Otherwise, if $\xi$ is not $\mu_{\alpha}$-generic, then we let $H_{\xi} = 1$. Let $\nu_{A}^{\alpha} = (f_{A}^{\alpha})_{*}\mu_{\alpha}$ be the corresponding ergodic IRS of $\text{Alt}(\mathbb{N})$. Finally, if $\alpha_{0} = 1$, then we define $E_{\alpha} = \emptyset$ and $\nu_{\alpha}^{E_{\alpha}} = \delta_{1}$.
Theorem 9.2. If $\Alt(\mathbb{N}) \curvearrowright (Z, \mu)$ is an ergodic action and $\nu$ is the corresponding stabilizer distribution, then the following are equivalent.

(i) The associated character $\chi(g) = \mu(\Fix_G(g))$ is indecomposable.

(ii) There exists $\alpha$ such that $\nu = \nu_{\alpha}^{E \circ \alpha}$.

The proof of Theorem 9.2 makes use of the following results of Thoma [15].

Theorem 9.3. (Thoma [15, Satz 6]) The indecomposable characters of $\Alt(\mathbb{N})$ are precisely the restrictions $\chi \upharpoonright \Alt(\mathbb{N})$ of the indecomposable characters $\chi$ of $\Fin(\mathbb{N})$.

Theorem 9.4. (Thoma [15, Satz 1]) If $\chi$ is a character of $\Fin(\mathbb{N})$, then $\chi$ is indecomposable if and only if there exists a sequence $(s_n : n \geq 2)$ of real numbers with each $|s_n| \leq 1$ such that $\chi(g) = \prod_{n \geq 2} s_n^{\alpha_n}(g)$.

Lemma 9.5. If $\Alt(\mathbb{N}) \curvearrowright (Z, \mu)$ is an ergodic action and there exists $\alpha$ such that the corresponding stabilizer distribution is $\nu_{\alpha}^{E \circ \alpha}$, then the associated character $\chi(g) = \mu(\Fix_G(g))$ is indecomposable.

Proof. If $\alpha_0 = 1$, then $\nu_{\alpha}^{E \circ \alpha} = \delta_1$ and the associated character $\chi_{\log}$ is indecomposable. Hence we can suppose that $\alpha_0 \neq 1$ and so $I \neq \emptyset$.

With the above notation, $\Fin(\mathbb{N})$ acts ergodically on $(\mathbb{N}^\mathbb{N}, \mu_n)$ and we can define a $\Fin(\mathbb{N})$-equivariant Borel map

$$\varphi_\alpha : \mathbb{N}^\mathbb{N} \to \Sub_{\Fin(\mathbb{N})}$$

$$\xi \mapsto \bigoplus_{i \in I} \Fin(B_i^\xi).$$

Let $\nu_{\alpha}^+ = (\varphi_\alpha)_* \mu_n$ be the corresponding ergodic IRS of $\Fin(\mathbb{N})$ and let $\chi_{\alpha}^+$ be the character of $\Fin(\mathbb{N})$ defined by

$$\chi_{\alpha}^+(g) = \mu_n(\{ \xi \in \mathbb{N}^\mathbb{N} | g \in \bigoplus_{i \in I} \Fin(B_i^\xi) \}).$$

Then it is easily checked that

$$\chi_{\alpha}^+(g) = \prod_{n > 1} (\sum_{i \in I} \alpha_n a_{i+}(g)).$$

Hence, by Theorem 9.4, it follows that $\chi_{\alpha}^+$ is an indecomposable character of $\Fin(\mathbb{N})$.

Notice that if $g \in \Alt(\mathbb{N})$, then

$$\chi(g) = \mu(\Fix_Z(g))$$

$$= \nu_{\alpha}^{E \circ \alpha}(\{ H \in \Sub_{\Alt(\mathbb{N})} | g \in H \})$$

$$= \mu_n(\{ \xi \in 2^{\mathbb{N}} | g \in \Alt(\mathbb{N}) \cap \bigoplus_{i \in I} \Fin(B_i^\xi) \}) = \chi_{\alpha}^+(g).$$

Applying Theorem 9.3, it follows that $\chi$ is an indecomposable character of $\Alt(\mathbb{N})$.

Proof of Theorem 9.2. Let $\Alt(\mathbb{N}) \curvearrowright (Z, \mu)$ be an ergodic action and suppose that associated character $\chi(g) = \mu(\Fix_G(g))$ is indecomposable. Let $\nu$ be the corresponding stabilizer distribution. If $\nu = \delta_1$, then $\nu = \nu_{\alpha}^{E \circ \alpha}$, where $\alpha_0 = 1$ and $E_0 = \emptyset$. Hence we can suppose that $\nu \neq \delta_1$. Applying Theorem 9.1, there exist $\alpha$, $A$ as above with $I \neq \emptyset$ such that $\nu = \nu_{\alpha}^{A \circ \alpha}$ and hence

$$\chi(g) = \mu_n(\{ \xi \in \mathbb{N}^\mathbb{N} | g \in H_\xi \}).$$
If $|I| = 1$, then $E_a = 0$ is the trivial group and so $A = E_a$. Thus we can suppose that $|I| \geq 2$. For each element $a = (\varepsilon_i)_{i \in I} \in A$, let $\sigma(a) = \{ i \in I \mid \varepsilon_i = -1 \}$.

If $A \neq 0$, let $m_A$ be the least integer $m$ such that there is an element $0 \neq a \in I$ such that $|\sigma(a)| = m$. If $A = 0$, then let $m_A = 0$. Let $g = (12)(34)$ and $h = (12)(34)(56)(78)$. Then Theorem 9.4 implies that $\chi(h) = \chi(g)^2$.

**Case 1:** Suppose that $m_A > 2$. Then it is easily seen that $\chi(g) = \sum_{i \in I} \alpha_i^4$ and that $\chi(h) \geq \sum_{i \in I} \alpha_i^8 + \frac{1}{2} \sum_{\{i,j\} \in |I|^2} \alpha_i^4 \alpha_j^4$. On the other hand, we have that $\chi(g)^2 = \sum_{i \in I} \alpha_i^8 + 2 \sum_{\{i,j\} \in |I|^2} \alpha_i^4 \alpha_j^4$ and so $\chi(h) > \chi(g)^2$, which is a contradiction.

**Case 2:** Suppose that $m_A \in \{0, 2\}$. Let $\Gamma = (I, E)$ be the graph with vertex set $I$ and edge set $E$ such that $\{j, k\} \in E$ if and only if there exists $a \in A$ with $\sigma(a) = \{j, k\}$. Then it is enough to show that $E = |I|^2$.

In this case, it is clear that $\chi(g) = \sum_{i \in I} \alpha_i^4 + 2 \sum_{\{i,j\} \in E} \alpha_i^2 \alpha_j^2$ and so

$$\chi(g)^2 = \sum_{i \in I} \alpha_i^8 + 2 \sum_{\{i,j\} \in E} \alpha_i^4 \alpha_j^4 + 4 \sum_{i \in I} \alpha_i^4 \sum_{(j,k) \in E} \alpha_j^2 \alpha_k^2 + 4 \sum_{\{i,j\} \in E} \sum_{\{k,l\} \in E} \alpha_i^2 \alpha_j^2 \alpha_k^2 \alpha_l^2.$$ 

After rearranging the terms, we obtain that

$$\chi(g)^2 = \sum_{i \in I} \alpha_i^8 + 6 \sum_{\{i,j\} \in |I|^2} \alpha_i^4 \alpha_j^4 + 4 \sum_{i \in I} \alpha_i^6 \alpha_j^2 + 4 \sum_{\{i,j\} \in E} \alpha_i^4 \alpha_j^2 \alpha_k^2 + 8 \sum_{\{i,j\} \in E} \alpha_i^2 \alpha_j^2 \alpha_k^2 \alpha_l^2.$$ 

On the other hand, we have that

$$\chi(h) = \sum_{i \in I} \alpha_i^8 + 6 \sum_{\{i,j\} \in |I|^2} \alpha_i^4 \alpha_j^4 + 4 \sum_{\{i,j\} \in E} \alpha_i^6 \alpha_j^2,$$

$$+ 12 \sum_{i \not\in \{j,k\} \in E} \alpha_i^4 \alpha_j^2 \alpha_k^2 + 24 \sum_{\{i,j,k,\ell\} \in T} \alpha_i^2 \alpha_j^2 \alpha_k^2 \alpha_\ell^2,$$

where $T$ is the set of $\{i,j,k,\ell\} \in |I|^4$ such that there exists $a \in A$ with $\sigma(a) = \{i,j,k,\ell\}$. Note that if $\{i,j\}, \{k,\ell\} \in E$ are disjoint edges, then $\{i,j,k,\ell\} \in T$. Also, each $\{i,j,k,\ell\} \in T$ can be partitioned into two disjoint edges in at most 3 ways. It follows that

$$\begin{align*}
(9.1) \quad 8 \sum_{\{i,j\} \in E} \alpha_i^2 \alpha_j^2 \alpha_k^2 \alpha_\ell^2 &\leq 24 \sum_{\{i,j,k,\ell\} \in T} \alpha_i^2 \alpha_j^2 \alpha_k^2 \alpha_\ell^2, \\
&\quad \text{for } i,j,k,\ell \text{ distinct}
\end{align*}$$

Clearly we also have that

$$\begin{align*}
(9.2) \quad 6 \sum_{\{i,j\} \in E} \alpha_i^4 \alpha_j^4 &\leq 6 \sum_{\{i,j\} \in |I|^2} \alpha_i^4 \alpha_j^4.
\end{align*}$$

Since $\chi(h) = \chi(g)^2$, the inequalities (9.1) and (9.2) must both be equalities and it follows that $E = |I|^2$, as desired. \qed
